The Lettsomian Lectures

160 p

[illegible] HEART [illegible] ADVANCED LIFE.

Delivered before the Medical Society of London on March 4th and 18th and April 1st, 1901,

BY J. MITCHELL BRUCE, M.A., LL.D. ABERD., M.D., F.R.C.P. LOND.,

PHYSICIAN TO CHARING-CROSS HOSPITAL; CONSULTING PHYSICIAN TO BROMPTON HOSPITAL FOR CONSUMPTION, &c.

LECTURE III.[1]

Delivered on April 1st.

MR. VICE-PRESIDENT AND GENTLEMEN,—In this the concluding lecture of the series I will attempt to deal with the applications of the facts and considerations which I submitted to you on the two previous occasions when I had the honour to address you. I trust that what I submitted to you then proved to be of some interest. Let us see now whether it is practically useful. However much the etiology and pathology of the diseases and disorders of the heart and arteries in middle and advanced life may deserve study as matters of natural history, we should be disappointed if they could not be turned to account in prognosis and treatment. These are the subjects which I propose to discuss this evening.

Now, prognosis and treatment, to be rational and useful, have to be based on as full and as correct a diagnosis as knowledge permits. The present disposition is to fall short of this, to rest cont[illegible] to diagnosis. We say that the patient's [illegible] "arterial degeneration," ar[illegible]eration." But you will remember that we have found that cardiac dilatation may be present in every kind of cardio-vascular degeneration, that the arteries are naturally enlarged and thickened after middle life, and that we refused to call these changes morbid. Clearly, therefore, a purely anatomical diagnosis of this sort is insufficient. If you are asked what the prognosis is of fatty degeneration of the heart you answer that [illegible] you must first be told whether syphilitic or gouty disease of the coronary arteries, or strain, or alcoholism, or phosphorus poisoning, or anæmia is the cause of it. [illegible] When you are planning the treatment of dilatation of the heart you first determine whether the dilatation is a result of the stretching of a sound heart by over filling during muscular effort or of the insufficient emptying of failing chambers with degenerated and feeble walls. Obviously what we ought to determine in these instances and in every instance is the origin of the disease. The ultimate diagnosis to be reached for practical purposes is the etiological diagnosis. Is this possible? Does our knowledge of the nature, characters, and course of these cardio-vascular affections enable us to say after investigating a case what the kind of the pathological change is that constitutes the disease or in what respect the physiological mechanisms are disordered? Can the cause of senile degeneration of the heart and arteries be determined in each instance? How is the practitioner to proceed to do so? What method might be followed with advantage in making a complete diagnosis of heart disease in older subjects?

A man, 60 years of age, consults us about his heart. He says that it has given him a good deal of trouble lately. More specifically he describes a sense of oppression behind the sternum as often as he exerts himself and palpitation with consciousness of irregular cardiac action when he goes to bed. We inquire for other familiar cardiac symptoms, such as pain, angina, fluttering, faintness, giddiness, and a sense of impending death. We find that one or more are present occasionally and that they have increased in number and degree during the last few months or years. Perhaps cough, nocturnal orthopnœa, and dropsy may be beginning to give trouble. The next part of the inquiry relates to the patient's previous history from childhood upwards. Which of the acute diseases has he had? Acute rheumatism, chorea, scarlet fever, typhoid fever, diphtheria, and influenza must be mentioned individually, and in women the nature of any puerperal disease from which they may have suffered. Gout, irregular gout, gravel, eczema, sick headache, and asthma must be inquired after with the same minuteness, and so must syphilis. We next hear an account of any accident which the patient may have met with, such as a blow or a fall from a horse or a carriage. This brings us naturally to question him about his occupation and modes of relaxation and amusements, whether active or sedentary, regular or irregular, their character [illegible] including strain. More [illegible] of the patient's habits [illegible] and tobacco, and his [illegible] said in my first lecture, [illegible] practitioner has an opportunity to carry out much more successfully than the hospital physician or consultant. The family practitioner has known for years of his cardiac patient's work and worries; it may be of his large eating, of his secret drinking, of the history of syphilis in earlier years. It is always well also to inquire after a family history of gout, rheumatism, and heart disease. A list of questions like this sounds far more formidable than it is in reality. A few minutes suffice to arrive at the truth. We already have a pretty fair notion what we have to deal with—whether strain, gout, syphilis, tobacco, an old rheumatic lesion, or a combination of two or more of these. We next proceed to physical examination, beginning with the pulse and arteries, and passing on to the heart and associated structures. The characters of the præcordial impulse, particularly the seat of the apex beat and the strength of the impulse, are closely—I might almost say laboriously—investigated. We must never yield to the temptation to disregard weakness or absence of the impulse. Like many other negative signs, it is apt to be overlooked. Then the præcordial dulness is mapped out by means of light percussion. Finally, auscultation reveals to us the presence or absence of murmurs and the characters of the sounds—in the standing and recumbent postures, and if necessary after a little exertion. The relative loudness of the first and second sounds over the different parts of the præcordia is particularly worthy of note.

Now let us suppose that we have found a mitral systolic murmur. We ask ourselves whether it is structural or whether it is functional—that is, due to relaxation and dilatation of the ventricular walls. If structural, with which (if any) of the diseases elicited in the man's previous history would it correspond? Most probably with gout or glycosuria. Thus we attempt to connect the lesion with its cause and the cause with its effects, and have reached the ultimate diagnosis. So with other valvular murmurs; for example, aortic diastolic murmur proves to be related to syphilis. If there be no murmur audible we naturally think of dilatation with failure, or of enlargement from strain, from Bright's disease, from arterial sclerosis, from emphysema, from an insufficient or impure blood supply in the coronary arteries, from disordered innervation, or from some rarer cause, such as adherent pericardium; and, again, with these associations in our minds we review once more the patient's history and ge[illegible] the principal signs and symptoms which I detailed to you in my last lecture, considered in the reverse order on this occasion, some of which are of real value in differentiating the causes of cardio-vascular degeneration. To begin with negative facts, a mitral presystolic murmur is never significant of a senile lesion. Secondly, when we meet with an aortic diastolic murmur, whether alone or along with an aortic systolic murmur, we may safely conclude that we have to deal with something more than atheroma produced by regular or irregular gout and associated metabolic disturbance, cardio-vascular disease of nervous origin, and alcoholic or tobacco heart, even if there be evidence of the presence of one or more of these in the case. Aortic incompetence developed in later life is the result of syphilis or of acute or chronic valvular strain; but of course many instances of this lesion met with after the age of 40 years can be traced to juvenile endocarditis of rheumatic or other origin. Always a serious lesion, aortic incompetence due to syphilis or to syphilis and strain is particularly grave as being so frequently associated with coronary disease and consequent myocardial degeneration—fatty or fibroid acute softening and sudden fatal failure. A fully-developed basic systolic murmur audible over the aortic area and manubrium and along the course of the carotid is a very common sign of atheroma of the aortic arch and valves and great vessels in association with regular or irregular gout, diabetes, corpulence, and allied disorders of nutrition. It is also one of the physical signs of syphilitic and traumatic affections of the aorta and aortic valves and of remote endocarditis. Further, these lesions are so often accompanied by similar degenerations in the coronary arteries and consequent myocardial degenerations that the basic systolic murmur ought, at least, to raise the suspicion of this in the observer's mind. An ill-developed basic systolic murmur is not uncommon in alcoholism, chronic Bright's disease, and nervous strain, but is difficult to dissociate from anæmia. A fully-developed and audible systolic murmur in the mitral area (I mean independently of ventriculo-auricular leakage in cardiac failure) is usually traceable to early endocarditis of rheumatic or other origin, rarely to injury, including ordinary juvenile strain of the valves or walls or to Graves's disease. In some instances it is unquestionably due to valvular atheroma and attendant sclerosis caused by gout or other disturbances of metabolism, including the effects of free living; and in these instances the observer must not overlook the possible association of coronary disease and fatty degeneration. If a systolic mitral murmur prove to be somewhat indefinite and affected by posture, cubitus, and effort, to vary under observation from day to day, and to disappear under treatment, it is of no more value to us in differential diagnosis than that it signifies relaxation and weakness, or disorderly action, of the left ventricle, consequent on any one of the recognised causes of failure or disturbance of the heart, including the different cardiac poisons, overwork, anæmia, acute disease, poverty, and the like, and this, whether in a heart previously sound, or previously enlarged, or previously the seat of valvular disease. An accentuated ringing second sound in the aortic area or more extensively is of great value in the diagnosis of arterial tension and aortic atheroma, or of both, but it is associated with far too many different causes to be of much use in differential diagnosis. It should suggest a most careful search for Bright's disease. Slight reduplication of the first sound is common over senile hearts strained in youth and hearts degenerated by alcoholism and metabolic disorders, and everyone knows that it is not unusual in a variety of other conditions, healthy and morbid. On the other hand, the *bruit de galop* or cantering rhythm of cardiac sounds—definite doubling of the first sound followed by loud, accentuated, ringing second sound—is practically pathognomonic of Bright's disease, and is one of the most valuable, because one of the most ominous, of physical signs in connexion with the cardio-vascular system. A normally sized heart with irregularity, increased frequency, and a variable systolic murmur in the mitral area is characteristic of tobacco poisoning. A heart enlarged on both sides and acting irregularly without murmur is, apart from cardiac failure, suggestive of strain in early life.

---

[1] Lectures I. and II. were published in THE LANCET of March 9th (p. 692) and 23rd (p. 844), 1901, respectively.

Cardiac symptoms taken individually are of less diagnostic value than signs. No symptom is pathognomonic. Palpitation is a nearly universal phenomenon of cardiac disease and disorder. Faintness and actual faints are not uncommon in cases of early cardiac strain, gouty heart, and nervous disturbances. Angina we meet with, you will remember, in regular and irregular gout, tobacco heart, strain (especially strain after the age of 40 years), and in syphilis and alcoholism, whilst pseudo-angina is extremely common in nervous women; thus it is of less diagnostic value than might have been expected. A high tension-pulse I have found most often in juvenile strain and cardio-vascular affections of nervous origin, a low-tension pulse in connexion with alcoholic and tobacco-poisoning and with senile strain.

When we review these facts I think we are entitled to conclude that the physical signs and symptoms carefully determined by clinical investigation may be confidently employed, along with the patient's previous personal history and the history of his present illness, to differentiate from each other the causes of cardio-vascular degeneration in individual cases; and, further, that they inform us of the seat of at least some of the lesions, valvular, parietal, and vascular. A little trouble, patience, and attentive observation are all that are required to reach a complete or working diagnosis. Now we may approach the great practical subjects of prognosis and treatment with some confidence.

PROGNOSIS.

Beginning with the simplest kind of cardio-vascular disorder let us see what the prognosis is in tobacco-heart. You will have gathered from what I had to say on this subject in my last lecture, and, indeed, you know as men of observation and experience, that it is comparatively favourable. All the cases I have had an opportunity to watch did well, provided the cause of their distress was avoided and the heart and vessels were otherwise healthy. Further, improvement begins early, and it may be rapid and recovery complete; but you will remember that one patient whose case I detailed to you continued to have alarming angina for six months after giving up tobacco. Recurrence attends resumption of the habit, and some of its votaries contrive to continue to smoke just short of inducing serious discomfort. Unless a successful effort at reform be made cardiac trouble continues indefinitely. But even then I cannot say that I have seen serious damage done by tobacco alone in sound hearts, nor arterial sclerosis, as has been stated by some authorities.

An entirely different and most unfavourable estimate is to be formed of the prospect of life in the alcoholic heart. Naturally a certain proportion of cases recover if the disease be of recent development, the condition uncomplicated, and treatment faithfully carried out. Unfortunately, as a rule, we have to deal with alcoholism in which all these conditions of success are wanting. The habit is established, other organs besides the heart are involved, other diseases than alcoholism are present, and the patient has neither the inclination nor the power to follow our advice. Cirrhosis, neuritis, and dementia complicate the cardiac degeneration, or, more correctly, it complicates one or all of these. Chronic Bright's disease is made to account for a number of deaths in the mortality returns that strictly belong to alcoholism. Occasionally the end comes suddenly from fatty degeneration or in the course of some acute disease; otherwise, as we have seen, by slow cardiac failure and dropsy.

Prognosis in gouty heart—including the heart of the man with goutiness, glycosuria, and other irregular forms of the disease—is a subject of considerable practical difficulty. In my last lecture I read to you a short account of the case of a friend of my own who had had occasional attacks of gouty angina for 40 years. And certainly a large proportion of the old ladies of 60 or 70 years of age whom you all have had as patients for years on end with weak heart and systolic murmur in the aortic area owe their disablement to gout, if my observations are correct. The lesion proper of the aorta and aortic valves in these cases is atheroma, but the damage is accompanied with repair in the form of sclerosis, which by increasing the loudness of the bruit adds unreasonably to our anxiety about the case. Equally certain it is that patients belonging to this class improve under treatment. Still, the condition of arrest cannot go on indefinitely. In addition to extrinsic dangers, particularly those of Bright's disease, cerebral thrombosis, and hæmorrhage and bronchitis, failure of the heart is liable to supervene and prove fatal from the gravest of all intrinsic causes—namely, coronary degeneration. As this increases the myocardium is steadily more and more impoverished, its contractile vigour declines, and residual dilatation of the chambers sets in with mechanical congestion of the viscera. Complaints of "the heart" increase, the breathing becomes oppressed, the face assumes more and more the characteristic "cardiac" appearance, and dropsy creeps up the lower limbs. Even then the prognosis is not hopeless, for undoubtedly a certain proportion of cases of dropsy in old persons with degenerated heart and vessels are still amenable to rational treatment. But the case has ionally a more dramatic termination. As I was able to to after my second lecture by a specimen from the um of Charing-cross Hospital a branch of one of the onary arteries that has been narrowed by atheroma for an efinite length of time, with consequent cardiac weakness and discomfort, may any moment become thrombosed rapi y, apparently in consequence of some passing or other unfavourable influence, just as in thrombosis degenerated cerebral vessels. Fatal angina is the result. This is a point of great practical importance—that sudden eath will occur in old gouty subjects, not from the lesion of which a basic or an apical systolic murmur is the evi and which causes us concern, but from associated coronary atheroma which we probably never suspect; indeed, that it may occur in those subjects with no murmur whatsoever to attract our attention and excite our fears.

Still more unfavourable must be the forecast in syphilitic lesions of the heart and vessels Of 18 of my cases in which the result was known only one half improved under treatment, and 20 per cent. of them died within a few years, some indeed within a few weeks of the discovery of their disease. Cardiac failure accounts for most of the deaths, whether developed gradually with dropsy, which proves to be intractable; or progressing rapidly with great cardiac distress, including angina; or occurring suddenly, as it often does Aneurysm makes its appearance in other instances of which the patient dies, or he is carried off by general paralysis or Bright's disease.

What prospect have we to hold out to the man who has strained the walls of his heart by muscular effort? I believe that one can speak with some confidence on this subject. The middle-aged patient who over-stretched his cardiac walls as a youth may be comforted with the opinion that the condition is not a fatal one. The average duration of 11 cases of this order I found to have been 30 years when they came under my observation; the minimum duration was nine years, the maximum 50 years. This last case deserves particular mention. The patient was first seen by me for failure of the heart with cardiac dropsy consequent on fresh breakdown after exertion during a holiday; and it is most encouraging to observe that compensation was restored by treatment and that now, 12 months after that event, the patient is not only alive but able to carry on light professional work. This case also illustrates what I have told you respecting the course of the affection and the prospect before the patients in long-standing strain—that there is continual liability to fresh embarrassment of the heart during exertion in which they appear to have a lasting inclination to indulge.

Neither is strain of the heart for the first time after the age of 40 years by any means so grave as might be expected. Of course, sudden muscular effort occasionally accounts for sudden death in old men. But it is astonishing how under such circumstances quite old persons do recover from conditions of extreme distress lasting acutely for half an hour—for instance, after running with a heavy bag to catch a train. The majority of my patients described their condition as improved after a time, but others relapsed; and on the whole the correct prognosis is that they must expect to remain variously disabled—that is, liable to præcordial distress and dyspnœa on more than moderate exertion or when subjected to circumstances of other kinds that tax the heart

Cardio-vascular disorder and disease referable to nervous strain, pure and simple, is amenable to treatment by complete and prolonged rest or relaxation in the majority of instances. Still, death may occur from sudden cardiac failure; or should advice be neglected or soon forgotten, as happens so frequently in these subjects, the attendant high arterial tension and vascular degeneration too often end in cerebral lesions with or without Bright's disease. Of chronic Bright's disease itself and the associated cardio-vascular changes in their prognostic aspects I need not speak except to say that along with syphilis it is by far the most hopeless of all these affections.

In attempting to forecast the life of a man who is the subject of cardio-vascular degeneration in middle or advanced life we must not forget the possibility of the intercurrence of acute disease. Here is a large subject for us as practical men—one far too large and important for discussion here: the effect, for instance, of the existence of enlargement of the heart and an irregular and thickened pulse on the prognosis of influenza, or, let us say, on the chances of a successful issue after operation Very naturally, unsound vessels and a murmur over the præcordia weigh heavily against the prospect of recovery from pneu- [illegible] mple, and yet how often do we not find a patient of the age of 70 years with [illegible] extending outwards [illegible] one or both of these disturbing conditions come safely through such an illness Here, again, I believe it is in greater measure the true nature of the old-standing disease, not the physical signs, such as irregularity of pulse or mitral bruit, that ought to be taken into account. A heart enlarged and a radial artery thickened by prolonged activity and nothing el[illegible] will suffice to carry a man safely through an attack of influenzal pneumonia; but what chance is there for the [illegible]ronic alcoholic under similar circumstances or for the subject of chronic Bright's disease?

So much for the general *prognosis* in *each* of these kinds of cardio-vascular disorder and disease. But it is the particular prognosis that we have to attempt to estimate—that is, the prognosis in the individual patient as he comes before us and asks us that trying question: What is my prospect of life and health? We have to do our best to apply such conclusions as those which I have just submitted to you, and at the same time to estimate as correctly as possible the man's personal condition, character, and disposition. After all that may be determined by an analysis of a large number of these cases the patient's prospects in disease of the heart of every kind, degeneration included, greatly depend on how he takes care of himself.

TREATMENT.

Not the least advantage of the etiological standpoint of our survey of the disorders and diseases of the heart and arteries in middle and advanced life is the rational as well as hopeful line of treatment which it enables us to pursue. On the whole we can control morbific influences far more than we can alter pathological processes, and, what is of equal or even greater importance, a knowledge of the causes of disease often enables us to prevent what we could not possibly cure For all that, the etiology of heart disease furnishes us with but one set of many invaluable indications for treatment We must have also a clear mental picture of the pathological anatomy of the conditions which we would attempt to modify—for instance, of the damage wrought by gout on the mitral valves and aortic arch, by syphilis on the coronary arteries, and by strain on the walls of the different cardiac chambers. No less necessary is it for the practitioner to take into account before proceeding to prescribe the clinical characters and course of the case in hand. As I have said more than once already, a large proportion of the distress, disabilities, and dangers attending degeneration of the heart are due to some additional or extrinsic disturbance—distension of the stomach, constipation, worry, or exertion, which alone, not the pathological condition, calls for therapeutical attention It appears, then, that the whole natural history of the diseases and disorders of the heart, and I might add of every individual case, has to be studied and the value of its different parts absolutely and relatively estimated before rational treatment can be ordered. How different will treatment be if ordered on these principles from the routine procedure of prescribing a little strychnia and digitalis for a man with oppression on exertion and a systolic bruit at the base of his heart.

Let us begin this part of our subject with a brief consideration of preventive treatment founded on a knowledge of the cause at work. Now the first thing to strike us about these unfavourable influences is the number of them that could be avoided or controlled successfully by simple exercise of the will. The toxic effects of tobacco, alcohol, tea, &c, are due to abuse, from thoughtlessness or ignorance, or from indisposition rather than inability to exercise self-control. The abuse of tobacco appears to create so much discomfort or even alarm, of a kind which the sufferer cannot fail to refer to its cause, that the remedy is effected automatically and no great harm is done. We seldom have to do more than confirm the patient's suspicions in this direction and recommend temporary abstinence from the cigarette or pipe and greater care in the future. With alcohol it is a different matter. Alcoholism grows by what it feeds on and our best efforts are often vain. The present is hardly an occasion for dwelling on this subject—the duty of the profession to their patients and friends in respect of the abuse of alcohol Still, I should not feel that I had discharged to the best of my ability, or in full conformity with my strong convictions, the duties of the honourable position which by your favour I occupy as Lettsomian lecturer if I did not urge you to exercise more fully than is at present exercised your personal influence to discourage habitual drinking. I believe (because I have found) that many men who are not open to arguments of an abstract kind can be made to pause and reconsider their manner of living by having a concrete presentment of their condition and its results placed before them —in plain English, by being thoroughly frightened. "Heart disease" is a powerful argument to employ with persons of this class and it is one that is also justified by the issues at stake. Of syphilis and the havoc that it works on the heart, the aorta, and the vascular system generally, but particularly within the nervous system, I need not speak. The profession, as I have said, is not yet sufficiently alive to it; what can the public be expected to do in the way of prevention? Gout, corpulence, and allied metabolic disorders, those fruitful sources of cardio-vascular disorders and atheroma, call for temperance not only in drinking but in eating. Whilst the question continues to be discussed which particular articles of food ought to be avoided by gouty individuals, let us all join in offering them one bit of advice of the value of which there can be no doubt—whatever they eat, to eat little. Moderation in amount is, speaking broadly, far more important than avoidance of the theoretical antecedents of uric acid, whether meat or milk or sugar. With the observance of this simple and wholesome dietetic rule must go attention to free elimination by all the excretory channels and the insurance of sufficient exercise and enjoyment of fresh air. If we wish to impress this consideration on our own minds and give effect to it in our practice let us call to mind for a moment the number of cases that I have submitted to you of atheroma of the aorta in stout, matronly women of sedentary habits—in whom, indeed, this kind of degeneration is quite as common as in men.

I have already said so much on the subject of cardiac strain that it is unnecessary and would be uninteresting to return to the question of the prevention of it. We have seen how often it occurs in the middle-aged or old subject by ill-considered attempts at athleticism. Moderation and due respect for age are the true guides to the useful enjoyment of exercise after 40 years of age. As for the evil effects of nervous influences on the circulation, in addition to anxiety, care, misfortune, and grief, which are usually beyond our control, nervous strain, as distinguished from simple hard intellectual work, often must be relaxed if cardio-vascular damage is to be prevented. I refer to the cases of persons in positions of great responsibility, with heavy, complex, prolonged duties, which they fail to overtake without exhaustion consequent on high pressure and excitement.

I would not have dwelt so long upon the measures calculated to prevent degeneration of the heart were it not that they have to be employed with equal strictness and perseverance in the treatment of cardio-vascular disease when it is already established and our assistance is sought with anxiety. The etiological indications have still to be respected faithfully; on this I need not dwell. The next question is, What can be done for the pathological changes wrought on the arteries and the valves and walls of the heart? In syphilitic lesions we do not hesitate to say that iodide of potassium should be given freely; it is a specific remedy of great value. Can the atheromatous process be influenced with equal or with any success? It depends on toxæmia and anæmia: the obvious indication is to purify and enrich the blood. This, at least in respect of gout, glycosuria, and corpulence, as we have just seen, must be effected by a thorough reform in every department of personal hygiene. Arsenic and moderate doses of iodides, combined with an excess of alkalies, are calculated to promote the same end. Dr. Mott has shown that atheroma, whether of valves or of vessels, can be traced in many instances to disease of the vasa cordis and vasa vasorum. This carries us a step forward in our quest for indications, but the practical conclusion remains that the healthy nutrition of the smaller arteries has to be restored by attention to the blood and the use of specific remedies.

So much for valvular and vascular lesions. There remains to be discussed the fulfilment of the greater indication for treatment, the one which directs and governs the employment of the most important and successful of all the measures comprised in cardiac therapeutics. This is the establishment and maintenance of compensation. The nutrition and activity of the myocardium can be increased and sustained by means of specific cardiac stimulants and tonics, such as strychnine, ammonia, and the digitalis group of drugs, with hæmatinics, stomachics, and laxatives to insure an abundant supply of wholesome blood, by the control of nervous influences—one of the conditions of healthy nutrition—and by the employment of the non-medical measures now so extensively used to increase the vigour and benefit the metabolism of the cardiac walls, particularly active and passive exercises and baths. Unfortunately, the time left at my disposal in this concluding lecture is not sufficient to justify me in entering into detail on this most interesting subject.

I have now sketched very broadly the rational treatment of these disorders and diseases as far as the object of it is to prevent the occurrence or the extension of them and to promote compensation of the disabilities which they produce. It remains for me to notice, also very briefly, the management of cardio-vascular degenerations when the heart fails or when it appears to fail and distress and danger demand more direct and immediate attention. I have said "when the heart *appears* to fail" of set purpose. I am anxious to direct your attention, if it be but for a moment, to the fact that in many instances where præcordial oppression, pain, palpitation, and faintness, with frequent small, irregular pulse, are significant of serious disturbance of the action of the heart there is no failure of the myocardium in the proper sense of the term, but only embarrassment of a temporary character. Do not conclude from this that I regard the disturbance of the heart as of little account. I have called it serious, for indeed the patient may perish of it. What I wish to maintain is that in cardiac degeneration of any kind, in chronic cardiac dilatation, and in the enlarged heart of Bright's disease and of emphysema, just as in ordinary valvular disease, attacks of distress, alarming both to patient and medical man, often occur which call for nothing more in the way of treatment than attention to some intercurrent influence—an indigestible meal, loaded bowels, a nervous shock, a thoughtless effort, a passing hardship or nervous strain. Digitalis and its allies, strychnine, alcohol, nitrites, iodides, and the rest, are out of place in such an event. Complete rest in bed, a carminative draught, calomel and saline purgatives, spare and highly digestible diet, reassurrance, and a little time are quite sufficient means of treatment.

When true failure occurs, manifested by the familiar phenomena of residual dilatation of the heart, mechanical congestion, and dropsy, a different set of measures are demanded. Now is the time to attend with expedition, energy, and completeness to the fulfilment of the three great therapeutical indications for the treatment of cardiac failure: to reduce the peripheral resistance, to increase the vigour of ventricular contraction and rehabilitate hypertrophy, and to remove arrears of work in the form of residual blood in the cardiac chambers, mechanical congestion of the veins and viscera, and dropsy of the integuments and serous sacs. Bodily rest, a light solid diet and a definite allowance of alcohol if required, active purgation with mercurials, salines, and jalap, and the exhibition of sufficiently large doses of digitalis or one of its congeners, in combination with saline and other diuretics,—these are the means calculated to attain the desired objects. You will not expect me to enter into the many details of the management of cardiac failure. It is not different in any important respect in the man of middle or advanced age with cardiac degeneration from what it is in an ordinary case of chronic valvular disease. Only on a few points do I desire to dwell. First, that we must not be afraid to purge these patients if necessary every morning. Secondly, that when the appetite flags and flatulence occurs, instead of slops a blue pill or dose of calomel should be given and light solids persevered with. Thirdly, that nocturnal restlessness and sleeplessness are to be met unhesitatingly with permission to spend the night in an easy chair by the bedside. Fourthly, that, according to my experience, acupuncture and drainage succeed perfectly in these senile cases with dropsy, as much as 10 pints or more of serum escaping in the course of 24 hours, to the complete and often lasting relief of the circulation.

THE NEED OF MORTUARIES.—An inquest was held at Chard on March 20th upon the body of a newly-born infant. Dr. T. S. Balfour complained that there was no public mortuary in Chard and he said that he had been obliged to conduct the post-mortem examination in the same room in which the mother lay and almost within view of her. The jury concurred with Dr. Balfour and at their request the coroner was desired to communicate with the Chard Town Council on the matter.

SCLEROTIC HYPERPLASIA OF THE PHARYNX AND NASO-PHARYNX.

BY A. BROWN KELLY, B.Sc., M.B., C.M. GLASG.,
SURGEON FOR DISEASES OF THE THROAT, NOSE, AND EAR, VICTORIA INFIRMARY, GLASGOW.

THE case upon which this paper is based is unique in my experience and in that of others, if one may judge from the unsuccessful result of an extensive literary search for references to a similar affection. I therefore believe myself justified in regarding the condition as a hitherto undescribed pathological entity which may not inappropriately be termed "sclerotic hyperplasia of the pharynx."

The patient was brought to me in August, 1899, by his medical adviser, Dr. R. T. Halliday, on account of enlargement of the uvula. He was then 34 years of age and was engaged in a shipbuilding yard. For about eight years he had been subject to slight attacks of sore-throat which had caused, however, no special inconvenience. Three years before I first saw him he began to feel something in the pharynx which he wished to expel; this sensation had gradually increased. Latterly choking fits had been excited by the "something" coming forward on the tongue or passing too far back, as was apt to occur while he was being shaved; he obtained relief in the one instance by pushing the offending body back with his finger, in the other by throwing forward his head. In either case if he did not at once succeed in getting it into its normal position he became panic-stricken and fell to the ground writhing. While in this state he lost control of himself and being a powerful man he was capable of doing great harm. He had, therefore, to avoid being in a crowd, and the barber and others had to be warned to stand clear of him at once should a choking fit set in. In addition, nasal respiration had been partially obstructed for a year, so that he was much troubled at night by the throat becoming dry. The patient was a tall, strong Highlandman who had had no serious illness and no venereal disease. His father and mother both lived to about the age of 70 years and left a family of 12 children, all of whom grew up to be adults.

On examination the pharynx presented a very striking appearance. The uvula was much larger than any I had ever seen and hung like a curtain, concealing the posterior pharyngeal wall. Its length was over one and a quarter inches, its width at the base was one inch, and in thickness it was also greatly increased. The shape and surface were in no way abnormal. The colour, however, was pale and the consistence was fibrous, so that the whole formed a firm unyielding mass.

On bringing the uvula forward on the dorsum of the tongue the posterior wall of the pharynx was found to present a peculiar aspect. A narrow tract of apparently normal tissue ran down the middle of the posterior wall. On each side of this, extending outwards to the lateral wall and incorporating with it part of the right, and the whole of the left, posterior faucial pillar, was a broad prominent band which was thicker in its outer part. These bands passed upwards into the naso-pharynx and downwards to the upper end of the œsophagus. Their consistence was that of muscle and they could be pushed *en masse* towards the middle line. Their colour was a uniform grey and their surface was perfectly smooth. Fig. 1 shows the pharyngeal aspect after uvulotomy. Examination of the naso-pharynx, which was possible only after uvulotomy, revealed marked changes (Fig. 2). The lumen of the cavity was reduced so as barely to admit a forefinger; this was the more striking in view of the patient's height (six feet two inches) and large build. The diminution in the space between the soft palate and postero-superior wall of the naso-pharynx was due partly to the continuation upwards over the latter of the bands above described and partly to thickening of the soft palate. The thickening on the roof, unlike adenoid vegetations, was least in the middle and most marked at the sides. Only a small portion of the septum and middle turbinates could be seen; the choanal arches and Eustachian orifices were concealed. The thickenings in the naso-pharynx, like those in the pharynx, were smooth, grey, and firm. By means of the laryngeal mirror the bands on the posterior wall of the pharynx were seen to pass downwards and to overhang the arytenoids, the sides of the epiglottis being in contact with the bands.

FIG. 1.

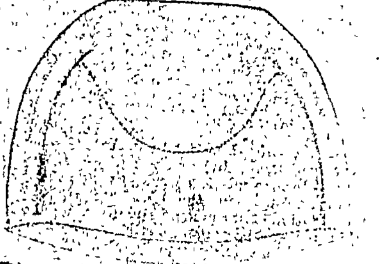

FIG. 2.

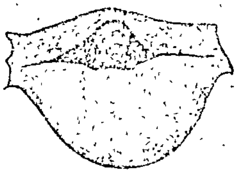
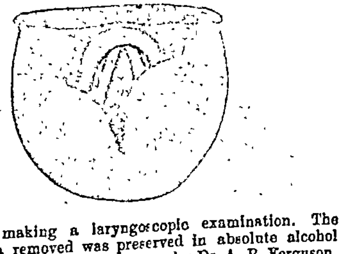


At a subsequent visit, in August, 1899, the greater part of the uvula was removed by means of the galvano-cautery snare without any untoward result. Since then the patient has experienced no discomfort and has considered himself cured. During the interval that has elapsed I have failed—except on the occasion noted below—to detect any change in the conditions described, and Fig. 1 and Fig. 2, which were made shortly after he came under my observation, illustrate the appearances at the present time. The occasion of the exception referred to was in October, 1900. After undue exposure he contracted a sore-throat which was more severe than any he had ever experienced. I saw him on the sixth day when the pain, which was confined to the left side, had begun to subside. There was then great swelling of the left band, especially about the level of the epiglottis; its surface was smooth and pale. Three weeks later the œdema had diminished considerably, so that a view of the larynx was obtainable; it was then found that the movement of the left arytenoid during phonation produced a clicking sound owing to its coming into contact with the overhanging tissues. Although five months have elapsed since this acute attack the left band continues rather thicker than the right and the clicking sound is still heard. Fig. 3 shows the appearances now observed on making a laryngoscopic examination. The piece of uvula removed was preserved in absolute alcohol and the report on its minute structure by Dr. A. R Ferguson, senior assistant to the Professor of Pathology in the University of Glasgow, follows:—

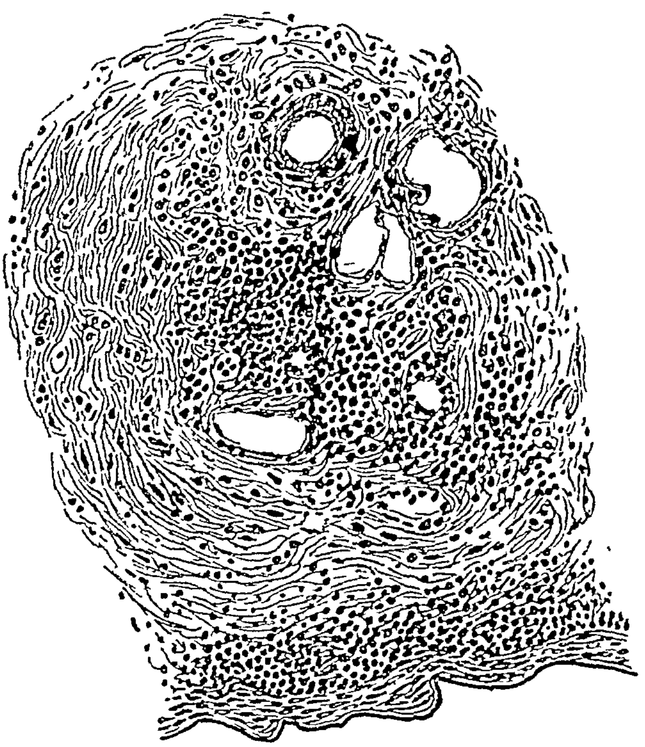
FIG. 3.



> The piece of uvula submitted was incised longitudinally and paraffin sections were prepared from each portion. The section represents the entire cut surface so obtained.
>
> *Low power.*—Almost the entire uvula is seen to consist of dense connective tissue of sparsely cellular character and fibrillated in appearance. This is disposed in denser whorls around the vessels, especially the arteries. Immediately surrounding the majority of the

vessels are dense areas of leucocyte infiltration. An irregularly distributed leucocyte infiltration is seen also running beneath the epithelial covering of the uvula. This latter is much compressed in appearance, the corneal layer especially being increased in thickness. The Malpighian layer shows no papilliform processes in any part

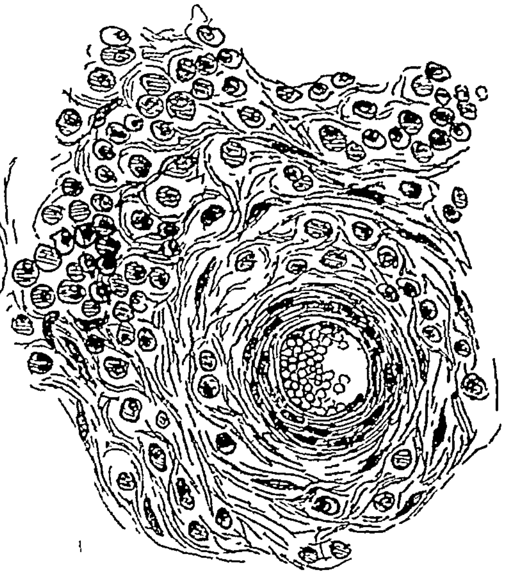
FIG. 4



(Fig 4) Occurring somewhat sparsely throughout the tissue are small groups of adipose vesicles, surrounded and in many cases diminished in size and separated by the dense connective tissue. Mucous gland tissue is abundantly present in the central portion of the uvula. The glandular tissue proper does not seem to have suffered to the same extent as the other portions in the prevailing fibrosis The interstitial tissue of the glands, however, is densely infiltrated with leucocytes which are disposed in irregular areas In the more central parts of the uvula the matrix of the connective tissue is more fibrous than at the periphery and the corpuscles correspondingly fewer in number. The vessels are small but comparatively numerous throughout; they are, without exception, surrounded by an irregular zone of leucocyte infiltration. A few striped muscle fibres, much interrupted and in great part completely isolated, are seen traversing that part of the tissue in which the glandular elements lie.

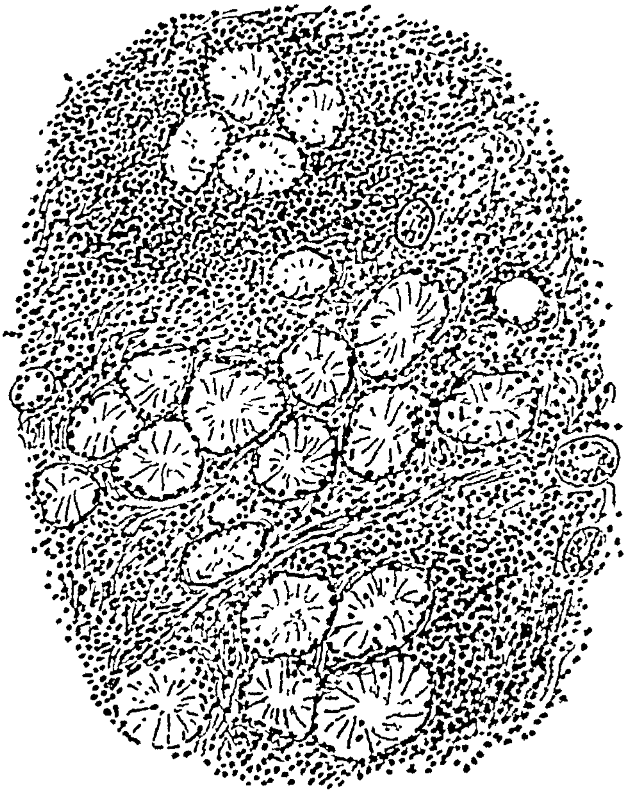
High power.—The epithelial cells of the surface are much altered by compression, having undergone a change comparable with that in the keratinous layer of the epidermis. The deeper layer shows no papillary processes, though the cells are well formed, their columnar character

FIG. 5.



being pretty well preserved. The tissue beneath this layer is a well-formed connective tissue which is finely fibrillated, the fibrillæ forming a very fine-meshed reticulum. The small vessels in this zone are surrounded by leucocytes. These latter are of the small mononuclear type mainly, though many polymorphonuclear leucocytes are also seen. The other cells present are connective tissue corpuscles, many of which are observed in process of division. In this zone of the connective tissue many of the corpuscles have an irregular form with delicate processes; in the main, however, they are of the spindle-shaped type met with in young developing connective tissue (Fig. 5). The fibrillar reticulum can still be distinguished in the midst of these cellular areas. The degree of leucocyte infiltration is more pronounced in the interstitial tissue of the mucous glands than elsewhere. The muciğenous cells show no alteration in appearance, the majority being collapsed with very indefinite outline (Fig. 6).

FIG. 6.



A small portion of the affected tissue was removed from the patient under conditions which precluded its contamination with micro-organisms from any source, and this, after having been cut into small pieces with sterilised scissors, was introduced into a series of sloped glycerine agar tubes. These showed in the course of the second 24 hours of incubation at 37° C. a few small colonies resembling in general appearance, but somewhat larger than, those of streptococcus pyogenes. Film preparations from these colonies showed a short, beaded bacillus which, in forms staining deeply at the extremities, resembled a small diplococcus. Nothing in the least suggestive of bacillus rhinoscleromæ was obtained in the cultures.

Microscopical sections of the uvula were stained by various methods for the demonstration of organisms—e.g., carbol—thionine blue, Loeffler's alkaline methylene blue, Kühne's blue, Gram's method. These, carefully searched, showed no bacillus to be present in the depths of the affected tissue in any part. A few organisms, however, resembling that briefly described above as having been obtained from cultures, were seen between and immediately beneath the deeper cells of the Malpighian layer of the mucous membrane and were only found in this situation. These, it is accordingly inferred, represent but accidental invasions from the surface. The whole condition may thus be briefly summarised, from the point of view of its morbid histology, as a chronic hyperplasia of the interstitial tissue of the parts involved, of apparently progressive character, with no tendency towards degeneration, and (so far as can be demonstrated) unassociated with the presence of any specific micro-organism.

This case presents three striking features—namely, the greatly enlarged uvula, the thick band descending in each half of the posterior wall of the pharynx, and the thickening of the roof and floor of the naso-pharynx leading to a marked diminution of its lumen. In all the regions affected the morbid process is apparently the same, consisting in diffuse uniform thickening, which histologically proves to be a marked interstitial hyperplasia. The development of the
disease has been very slo [illegible]

in this case could be found. The fact, also, that rhinoscleroma has been observed in this country only in persons who have come from districts in which the disease is endemic renders it highly improbable that my patient's ailment is of this nature. Lastly, the absence of the specific bacillus and of Mikulicz's cells almost conclusively disproves rhinoscleroma.

2. *Tertiary syphilis*, owing to the various aspects it may assume in the throat, naturally suggests itself. Inquiry as to the patient's previous health yields no indication of his ever having contracted venereal disease; besides, this morbid process differs from tertiary syphilis in its perfect symmetry, in the absence of any tendency to ulceration, and in its being uninfluenced by iodide of potassium.

3. *Hereditary syphilis.*—Recently I have had under treatment a boy, aged seven years, the subject of late hereditary syphilis. In addition to laryngeal manifestations his palate and uvula presented a smooth uniform thickening which, although less marked, resembled that of the case under consideration. The greater part of the uvula was removed and Dr. Ferguson found, on examining it microscopically, that the enlargement was due to a diffuse fibroid hyperplasia which in its main features closely resembled the histological appearances presented in sections from the case the subject of this paper.

In consequence of the similarity of the histological appearances in the two uvulas it has been necessary to consider—(1) whether the man is the subject of late hereditary syphilis, and (2) whether the sclerotic hyperplasia in the child is independent of syphilis.

I have failed to discover any fact in support of the first question. The patient's parents spent their married life in the Highlands and had a family of 12 children, all of whom reached adult life, the physique of every member being above the average. The patient is the second youngest child and presents none of the stigmata of the diathesis. Owing to the want of corroborative evidence in the personal and family history of the patient, and because of the general dissimilarity of his pharyngeal manifestations to those observed in hereditary syphilis, I believe that this disease may be left out of account as an etiological factor.

The second question, as to whether the involvement of the pharynx in the boy is independent of syphilis, must be answered in the negative. That he suffered from hereditary syphilis when an infant is beyond doubt. It is also evident that the affection of his pharynx is of the same nature as that of his larynx and that the latter resembles the diffuse hyperplastic infiltration of the larynx which has been described in a few cases of hereditary syphilis. On these grounds the hyperplasia of the boy's uvula may be attributed to the diathesis.

While I have been unable to find a disease of which the sclerotic hyperplasia in the man is a manifestion, I would point out that an analogous condition probably exists in subglottic hypertrophic laryngitis. This affection is usually characterised by the presence of pinkish, smooth, firm, symmetrical folds beneath the vocal cords, which develop slowly, apparently in consequence of recurrent inflammatory attacks, during which they become more or less swollen. If we now turn to the case under discussion we find folds of thickened tissue in the pharynx presenting characters similar to those just mentioned; we get a clinical history of his having been subject to sore-throat for years, and of permanent symptoms due to hypertrophic changes having set in only at a comparatively recent date; examination during an inflammatory attack revealed marked swelling of part of the affected region; and, lastly, Dr. Ferguson informs me that A. Sokolowski's[1] account—which is probably the most detailed and thorough—of the histology of subglottic hypertrophic laryngitis might stand for that of the removed portion of the enlarged uvula, the sole difference being that in our case the deeper layer of the epithelium is not thrown into papillæ, but presents practically an even continuous surface, the columnar character of the deepest cells of the rete Malpighii, however, being maintained.

Considerable discussion has taken place as to the nature of lottic hypertrophic laryngitis. In most text-books the ntioned are tuberculosis, syphilis, and rhino- he last being probably the commonest. Of 100 recently reported by A. Baurowicz[2] 34 were affected with subglottic hypertrophic laryngitis. If the frequency of subglottic hypertrophic laryngitis in scleroma be coupled with its great rarity apart from this disease it can be understood how certain observers who live where rhinoscleroma is prevalent—e.g., P. Pieniazek[3] and Baurowicz of Cracow—and who consequently see subglottic hypertrophic laryngitis comparatively often, maintain that it is *always* a manifestation of scleroma. On the other hand, Sokolowski of Warsaw, who has also had an extensive experience of rhinoscleroma, denies this, and proves incontestably, as it seems to me, that subglottic hypertrophic laryngitis may develop independently of scleroma, tuberculosis, and syphilis; he thinks that the morbid process is of a specific nature, the etiological factor being as yet unknown, but he suggests that hereditary syphilis may play a part. A. Kuttner[4] reports a case of subglottic hypertrophic laryngitis in which there were no grounds for suspecting the presence of any of the infective diseases mentioned; he maintains, therefore, that this laryngeal condition may appear as an affection *sui generis* which he proposes to term the genuine form of chorditis vocalis inferior hypertrophica. F. H. Bosworth[5] also states that there can be no question of a simple idiopathic inflammatory process in the subglottic region giving rise to marked hypertrophy, but he thinks that in most instances a diathetic condition is present. There are thus good reasons for according to subglottic hypertrophic laryngitis independent rank amongst the diseases of the larynx.

The facts brought forward in this paper, if correctly interpreted, prove (1) that the pharynx and naso-pharynx may be the seat of a sclerotic hyperplasia unconnected with syphilis, rhinoscleroma, or other known infective disease; (2) that a similar morbid process may manifest itself beneath the vocal cords as subglottic hypertrophic laryngitis; and (3) that in the hyperplastic variety of hereditary syphilis the histological appearances closely resemble those of the above described sclerotic hyperplasia.

Glasgow.

ON THE EXISTENCE OF IMMUNITY AFTER ENTERIC FEVER.

BY BURTON A. NICOL, M.R.C.S. ENG., L.R.C.P. LOND.,
CIVIL SURGEON ATTACHED TO THE ROYAL ARMY MEDICAL CORPS, SOUTH AFRICAN FIELD FORCE; LATE HOUSE PHYSICIAN, CHARING-CROSS HOSPITAL.

THERE seems to be a very general impression that an attack of enteric fever confers some degree of immunity upon the patient against further attacks of the same disease. The number of patients whom I found suffering from enteric fever in South Africa who had previously contracted the disease in India or elsewhere has made me feel that this conclusion is not based upon very good evidence.

A nursing sister of my acquaintance had two attacks of enteric fever in England during her nursing career, and she contracted the disease for the third time whilst doing duty with the forces in South Africa. An officer had suffered from enteric fever in India, and he also contracted malaria in that country. During the campaign he again became a victim and his illness was followed by three distinct relapses. These relapses did not occur in the usual way during the week or so after the temperature became normal, but came on when the patient was on an improved diet and beginning to get about—i.e., from three to five weeks after the temperature had fallen. This was, of course, altogether an unusual case and may have been complicated by his malarial diathesis. The following two cases are interesting as showing that the supposed immunity produced by very severe attacks of enteric fever was not sufficient to protect the patients for more than six months from a recurrence of their illnesses.

CASE 1.—A civil surgeon, aged 30 years, previously in good health, was admitted to No. 7 General Hospital at Estcourt in May, 1900, with symptoms of enteric fever. The attack was a most virulent one, the patient suffering from

very active delirium during the whole time that the temperature was raised. He had eight distinct hæmorrhages within a few days and the collapse produced by loss of blood was so extreme that he was not expected to recover. The temperature for about a week was between 103·5° and 105°F. He rallied, the temperature fell to normal on the eighteenth day, and from that time he made a good convalescence. He was sent home to England and after spending a month at home he returned to duty. His blood was examined during the illness for the Widal reaction; the clumping and loss of motility of the bacilli were instantaneous. In November, 1900, whilst doing duty at No. 14 General Hospital at Newcastle, this patient again went to bed with every symptom of enteric fever. He had headache, diarrhœa, and during the first week considerable delirium. The temperature ranged for some days between 103° and 104·5° and did not become for 30 days. A very typical roseolar eruption appeared over the whole front of the chest and the abdomen, the back, and the extremities, thus covering every part of the body with the exception of the head and neck. Although the illness was rather a long one it was not regarded as being unusually severe in type and the patient again made an uninterrupted recovery. The Widal reaction was again tried, this time about 10 weeks after the temperature fell. The result was a positive reaction, clumping and loss of motility taking place in about 20 minutes with the usual dilution.

CASE 2.—A private in the 2nd Middlesex Regiment, aged 24 years, was sent from a field hospital to No. 7 General Hospital at Estcourt in April, 1900. On admission he had a temperature ranging from 102° to 103·5° F., was typhoidal in appearance, and had a slight abdominal rash, abdominal fulness, and diarrhœa. The type of enteric fever was considered to be quite of average severity. His temperature fell to normal on the twenty-second day, but after remaining normal for four days it again rose, finally falling on the thirty-fourth day of the illness. Beyond this relapse there were no complications. He made a good recovery and was discharged to the convalescent depôt. This patient ought to have gone to England, but some mistake was made, and after remaining at the convalescent depôt for a month or two he was with others sent back to his regiment at the front. In September, 1900, he again had symptoms of enteric fever and was sent into hospital at Newcastle. On this occasion the attack was quite a mild one, and there was no relapse or any sort of complication. The temperature never went beyond 103° and fell to normal on the nineteenth day. He made an uninterrupted convalescence and on this occasion was sent to England. The Widal reaction was not attempted with this patient in either illness.

In these two cases the attack may have been due to an auto-infection. It is quite conceivable that the bacillus may remain within the body quiescent for many months and only become active at some time when, owing to fatigue, exposure, or other causes the bodily resistance to disease is temporarily lowered. If the natural immunity acquired by a very severe attack of the disease is of any value, however, the patient ought to be protected against the disease whether the cause comes from within or from without. One would also expect to find the degree of immunity varying directly with the intensity of the primary attack.

It is acknowledged by most observers that immunity acquired in this manner, if it exists, is much less pronounced and of more doubtful duration than that produced by other febrile disorders, such as small-pox, scarlet fever, &c. The question of its existence is of considerable importance at the present time as the possibility of procuring an artificial immunity by the present method of inoculation is at least doubtful, if we are not satisfied that an attack of the disease itself protects its victim against further onsets.

The clinical evidence upon the point is necessarily weak. Under ordinary circumstances the cause of the disease is only very occasionally present, and when it is present the predisposing circumstances favouring its development may be entirely absent. The large majority of the population at home, therefore, escape the disease altogether, and it is consequently not surprising if very few of those who have had the disease once contract it a second time. The present campaign will not throw any light upon the problem, as no systematic inquiry has been made as to whether the patient has or has not suffered from previous attacks of enteric fever. Most medical officers, however, have gained the impression that second attacks of enteric fever are fairly frequent, and even third attacks are not unknown. The peculiar frequency of relapses make the consideration of possible immunity much more complex. If the disease produces in its subject changes in the blood-serum antagonistic to the bacilli or their products one would not expect to find relapse so common a phenomenon in the clinical picture.

The experimental or laboratory evidence of an immunity existing consists mainly of the fact that the blood-serum of a patient who is suffering from enteric fever or who has had the disease recently has the power, even when considerably diluted, of interfering with the motility of Eberth's bacillus, and producing that characteristic clumping or agglutination of the bacilli which is known as the Widal reaction. This reaction is a very variable one. The same result has been obtained with the blood-serum of patients suffering from influenza, pneumonia, acute miliary tuberculosis, &c., and the suggestion that these patients at some time in their previous history have suffered from an undetected or abortive attack of enteric fever does not seem altogether to meet these cases. The reaction is also obtained with the serum from patients suffering from bacillus coli infection. The serum of the normal subject if not sufficiently diluted is also not without its effect upon Eberth's bacillus and there is no constant ratio at any time between the intensity of the disease and the intensity of the reaction. Various observers have recorded cases presenting clinically all the appearances of enteric fever but in which the blood-serum gave a negative reaction.

The Widal test is doubtless of great value from a diagnostic point of view, but the very striking fact that serum from patients who have been inoculated produces loss of motility and clumping of bacilli is certainly no guarantee that an artificial immunity has been produced in these cases. A very large number of the cases of enteric fever occurred in young soldiers soon after their arrival in South Africa and amongst these were many who had been inoculated on board ship during the voyage out and in whom the protection being so recent ought to have been particularly good. The very first case admitted into No. 7 General Hospital at Estcourt was one of our own orderlies suffering from enteric fever; he had been inoculated some three weeks previously during the voyage out.

It seems to me that at present there is no proof existing of the presence of an immunity after an attack of enteric fever. Immunity varies so much in different diseases and in different individuals: erysipelas leaves behind it apparently a predisposition to further attacks; diphtheria and pneumonia as far as we know give no protection; whilst an attack of one of the exanthemata usually protects its subjects very effectually. What place enteric fever is to take in this respect has still to be determined. My recent clinical experiences have led me to doubt the existence of any immunity in many cases. A large number of men in this campaign have, however, quite escaped the onslaughts of enteric fever and it is reasonable to think that all must frequently have been exposed to the risks of infection. If we can discover the reason for their resistance to the disease we may then hope to discover some method of general protection. Statistics may show that inoculation is a step in the right direction, but meanwhile we should not forget that the teachings of sanitary science to-day point out clearly many paths along which efforts at prevention can be successfully made.

THE PATHOLOGY AND TREATMENT OF RHEUMATOID ARTHRITIS.

BY P. W. LATHAM, M.D. CANTAB.,

FELLOW AND LATE SENIOR CENSOR OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; CONSULTING PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THE obscurity which envelopes the pathology of rheumatoid arthritis and the doubts which are entertained as to the effects resulting from the administration of drugs induce me to invite further attention both to the pathology and the treatment of this disease.

Notwithstanding the fact that the dystrophic or neural theory is said to be unsupported hitherto by any positive evidence of *morbid change in the nerve cells of the* spinal cord or in the nerves which supply the joints, I can find no evidence in post-mortem records that either the spinal cord or the sympathetic ganglia have been so carefully examined by modern methods and appliances as to justify pathologists in asserting that in rheumatoid arthritis these parts are healthy and free from organic change. Until Heine[1] formulated his views of the nature of the lesions accompanying infantile paralysis, based solely on an analysis of the symptoms, the lesions in the spinal cord in this disorder were overlooked; they were, however, readily recognised afterwards in a certain number of necropsies when attention had been called to the matter. I venture to think that the clinical symptoms also in rheumatoid arthritis furnish undoubted evidence of pathological change in the nervous centres, the exact nature of which can only be determined by further microscopical investigation. Furthermore, I shall endeavour to show that this view is supported by the results of treatment directed specially to the nervous centres.

Leaving out of consideration for the present the causes which induce changes in the joints themselves I would point to the distinctly neurotic character of the antecedents and accompaniments of the arthritic trouble. As antecedents there are the neuralgic pains, so often wrongly termed "rheumatic," affecting one or more of the limbs, the feeling of weariness or of numbness or tingling, symptoms to which Dr. Spender has called attention, sometimes affecting only one nerve or the whole of one limb, sometimes being localised along the spine or across the loins. According to Trousseau and Remak in women the disease is often preceded by megrim. Not unfrequently worry, anxiety, or shock appear to have been the factor originating the disease. As an accompaniment of the arthritic mischief we see the marked atrophy of the muscles which in many cases supervenes and is developed much more quickly than can be attributed to mere disuse. In fact, in some cases, as Dr. Ord has pointed out, "the muscular wasting precedes the osteo-arthritis." Now it seems incredible that this muscular atrophy, if it has lasted for any time, whether it be primary or secondary, can exist unassociated with degenerative changes in the spinal cord, and it is reasonable to assume that such changes are similar to those associated with infantile paralysis or with chronic anterior polio-myelitis, in which we have material lesions of the cord involving the antero-lateral columns, marked proliferation of the connective tissue elements, with swelling and subsequent pressure upon and atrophy of the anterior roots of the nerves supplying the affected muscles, with more or less complete disappearance of the multipolar cells, changes which in many cases can only be discovered when carefully sought with the aid of the microscope.

"Pathological facts appear to show that the trophic nerves of the bones and joints are found in the mixed nerve trunk and that they issue along with the motor fibres from the anterior cornua where they are, like the muscular trophic fibres, connected with a group of large caudate cells. It is impossible to say at present in what way these trophic fibres and cells are connected with the brain, but some connexion doubtless exists."[2] With regard to the nature of the injury which will give rise to active muscular atrophy, 'it seems now generally admitted that both irritative and destroying lesions of the ganglion cells of the anterior horns of the spinal cord, and their homologues in the medulla oblongata, pons, and crura, or of the efferent fibres which unite these cells with the periphery may give rise to active atrophy of muscle. But whether the same kind of cell exercises both motor and trophic functions, or there exist separate cells for each function, is as yet undetermined."[3] In infantile paralysis, however, the changes in the bones and in the joints are of a different character to those of rheumatoid arthritis, nevertheless clinical experience has taught us that injuries to the spinal cord or even to the nerves of a limb will set up arthritic changes which cannot readily be distinguished from those seen in the earlier stages of rheumatoid arthritis. Dr. Weir Mitchell, Dr. Moorhouse, and Dr. Keen were the first to call attention to the effect of nerve injuries on the nutrition of the joints. The symptom occurs within a few days after the injury to the nerve. "It consists essentially in a painful swelling of the joints which may attack any or all of the articulations of a member. It is distinct from the early swelling due to the inflammation about the wound itself, although it may be masked by it for a time; nor is it merely a part of the general œdema which is a common consequence of wounds. It is more than these—more important, more persistent. Once fully established, it keeps the joints stiff and sore for weeks or months. When the acute stage has departed the tissues about the articulations become hard, and partial ankylosis results, so that in many cases the only final cause of loss of motion is due to this state of the joints. Of all the agencies which impede movement it is the most difficult to relieve. Were we asked to state in what essential respect these lesions differ from subacute rheumatic disease of the same parts, we should certainly be at some loss to discern a difference."[4] In a subsequent work[5] Dr. Weir Mitchell again refers to the curious arthritic changes which may follow dislocations, ball-wounds, contusions, or even compressions of the nerves. "We may have one articulation—and if only one, a large one—involved, or perhaps all the joints of a finger, or every joint in the hand or of the entire limb may suffer. The swelling is never very great, the redness usually slight, and the tenderness on touch or motion exquisite. This condition of things remains, with little change, during weeks or months and then slowly declines, leaving the joints stiff, enlarged, and somewhat sensitive, especially as to movement. A small proportion of such cases find ready relief, but in many of them the resultant ankylosis proves utterly unconquerable, so that it is vain to break up the adhesions under ether, or to try to restore mobility by manipulation on splints. All alike fail and serve only to add to the essential tortures of the accompanying neuralgia and hyperæsthetic states of skin. Since writing my last paper I have met with some of the former patients who suffered with these troubles, but in no case originally very severe was there any great gain; indeed, in most of them the joints had become every year more stiff and useless. It is then quite clear that injuries of the spine, diseases of this organ and of the brain, and wounds, or any form of lesions of nerves, are capable of developing in the joints inflammatory conditions, usually subacute, and which so precisely resemble rheumatic arthritis in their symptoms and results that no clinical skill can discriminate between the two." The following case is recorded by Sir William Gull[6]:—

[illegible]

the ankles, though there was no obvious want of muscular power or any affection of sensation in the upper extremities. Tongue clean. Pulse 120. No acid perspirations. Urine high coloured, free from deposits, of normal quantity. The nerves of the surface generally were hyperæsthetic to a slight touch but deep pressure gave less inconvenience. The treatment consisted of good nourishment, wine and brandy freely administered, and opium to allay pain and overcome sleeplessness. The pulse gradually acquired more power, and sank to 80 The affection of the joints continued in varying degree through March, April, May, and June. From the beginning of April, there was an improvement in the power over the legs The same treatment was continued throughout, without the use of mercurials, local depletion, or counter irritation. In June the patient was able to walk without assistance. During sleep the hands and feet, wrists and ankles, often become erythematous and swollen. There was occasional formication in the lower extremities. Sleeplessness, from the beginning of the case and throughout, was a troublesome symptom. In July the patient was able to leave the hospital and to resume to some extent his duties as medical practitioner. He was under the care of my colleague, Mr. Cock.

Further we have the arthropathies consecutive on lesions of the nervous centres, cerebral and spinal, which Scott Alison, Brown-Séquard, and Charcot have described, the tumefaction, redness, and pain of the joints closely simulating acute rheumatism or gout. So far back as 1831 Professor J. K. Mitchell[7] reported some cases of a striking character

in which arthritic symptoms supervened upon injury to the spinal cord. These cases were successfully treated by applying from eight to 16 cups, abstracting about as many ounces of blood from the neighbourhood of the cervical or lumbar enlargements, according as the upper or lower extremities were affected, and if the cupping did not afford relief applying blisters to the same regions. The following most interesting case, which came under my observation in Cambridge, illustrates, I think, very well the development of arthritic mischief from irritation of the central nervous system, the irritation being chiefly localised in the medulla oblongata and affecting the vaso-motor centre. It further illustrates the beneficial effects of Professor Mitchell's plan of treatment by cupping and blistering.

J. W., aged 54, a labouring man, was working on a stack in the dusk of early morning on Dec. 24th, 1885, when he fell, dropping about eight feet, on to his left side. He walked home, with pain and difficulty, a distance of over a mile; he went to bed, lay there drowsy and without appetite, very helpless, and only just able slowly to move his limbs. After remaining a week in this condition he was carried into Addenbrooke's Hospital on Dec 31st, 1885, under Mr. G. E Wherry, to whom I am indebted for an opportunity of seeing the patient, as well as for the notes of the case. When admitted he was drowsy and stupid, and answered questions in a dull manner when roused; cutaneous sensation seemed everywhere perfect; movements of the limbs were very slow, difficult, and painful; turning over in bed was a struggling tedious process. The grip of the hands was very feeble, especially the right; no rigors, no sweats; no bladder symptoms Bowels confined. His health had always been good, and he was working daily up to the date of his accident. Jan. 1st, 1886.—Some swelling of the left wrist and fingers, and both ankle-joints, with pain on movement, and tenderness; relieved by an opiate. Heart-sounds normal. Evening temperature, 101·6° F. Jan 2nd.—Marked swelling and redness of the left wrist-joint and of the joints of the first and second fingers, with œdema, and angry red appearance of the back of the wrist Slight swelling also of the right wrist and finger joints It was extremely tender, and looked as if it would suppurate. Beads of sweat on left forehead; a few small herpetic vesicles are seen along the course of the left supra-orbital nerve; tears and secretion excessive in conjunctival sacs of left eye; pulse 80; considerable œdema of both ankles. Patient is drowsy, and sleeps except when roused by pain. No general sweating; urine acid. Bowels open by calomel. Evening temperature 101·4°. Jan. 3rd.—Redness and swelling in left wrist continues, as well as in both ankles; drowsiness and stupor; muco-pus in conjunctival sacs of left eyelids, not in the right. The knees usually drawn up in bed, of which movement he does not seem conscious; he can put them down by an effort. Morning temperature, 100·2°, evening, 101·8°. After consultation with Dr. Latham he was cupped at the root of the neck behind in two places, about two ounces of blood drawn; no relief that night. Evening temperature, 101·8°. Jan. 4th.—He seemed better and in less pain. Morning temperature, 100·2°; evening temperature, 101·6°. Jan 5th.—Less pain and tension in the joints; morning temperature, 99·2°. His manner still stupid and dull. Two cups were applied near the lower cervical vertebræ and two near the lower dorsal vertebræ and about four ounces of blood drawn. He was ordered to take at once five grains of calomel and one grain of opium, and a black draught the following morning if necessary. Evening temperature, 101°. Jan. 6th.—Better. Morning temperature, 100°; wrists and ankles less swollen. Bowels open three times after the calomel. Evening temperature, 101°. Ordered tinct. opii (20 minims) at bedtime. Jan. 7th.—Wrists and ankles better. Complains of pain in right knee, with some tenderness, but there is no swelling. Morning temperature, 100·4°; evening, 100·8°. Ordered four blisters, 1½ × 1½, to four spots along the spine, to be kept open with savine ointment. Opiate to be taken every night Jan. 9th.—The right foot and ankle more painful and swollen. The other joints better. Morning temperature, 101·2°. Ordered a blister, 4 × 3 inches, over the lower dorsal vertebræ Evening temperature, 101·8°. Jan. 10th.—Feels better; has had a good night, has no longer the dull, stupid manner, mind clear, was ordered tinct. opii (10 minims) three times a day; the blister to be kept open with savine ointment. From this time continuous improvement took place. The evening and morning temperatures fell daily until the 19th, when the evening temperature reached the normal point, and the blistered surfaces were allowed to heal. There was some œdema about the affected joints after the redness and pain had passed away, but this entirely disappeared by the 23rd. There was still at this date a little tenderness and thickening about the left wrist. The unilateral sweating of the face was noticed from time to time. Feb. 2nd.—The patient's condition much improved Is sitting up. Has lost all pain, except now and then in left wrist. There is some thickening and stiffness about the joints which were affected, and his grip is still weak, though very much stronger than before

Upon the foregoing data it is not unreasonable to assume that the joint troubles in rheumatoid arthritis are due to spinal congestion or chronic myelitis chiefly affecting the ganglion cells of the anterior horns, but extending also, when the disease is associated with "glossy skin," to the ganglion cells in the posterior horns[8] If this is the case the natural inference would be that, in the earlier stages of the malady, at all events, the treatment should be directed to the abatement of this spinal congestion and that probably this can be most effectively done by cupping or blistering the spine. On these grounds, therefore, this plan of treatment was adopted in the following cases.

CASE 1.—A farm-labourer, aged 19 years, was admitted into Addenbrooke's Hospital on Jan. 8th, 1896. He had always enjoyed good health until September, 1894, when he was suddenly seized with pain in the left chest, which was soon followed by pain in both knees and shoulders, but without any swelling of the joints. He remained in bed for a fortnight and at the end of eight weeks he resumed his work, feeling quite well and with no shortness of breath. He remained quite well until 10 weeks previously to being admitted into the hospital, when, without exposure to cold or any other assignable cause, the right hip became painful. The pain spread to both knees, shoulders, feet, and hands. For the last 10 days all the joints of both hands had been swollen and for a week the ankles also had been swollen. The patient had a dark complexion and a healthy aspect. The skin was hot but not perspiring. There was no rheumatic odour. The tongue was clean and the bowels were regular. In the left axilla there was an enlarged gland of the size of a walnut and another of smaller size in the right axilla. There was a soft systolic murmur at the heart's apex, with an accentuated pulmonary second sound. The wrists, the knees, and the ankles were swollen, distended with fluid, and painful. All the phalangeal joints were tender and swollen. There was pain in the left shoulder and in the left side of the neck which was increased on movement. The patient's temperature on admission and for some 10 weeks varied between 100° F. in the evening and 99° in the morning, and the remedies employed (though without much advantage) were bark, salicylates, colchicum, quinine, and iodide of sodium, cod-liver oil, and arsenic. About the middle of May a normal temperature was reached. Arsenic was prescribed after meals, and iodide of sodium and bark in the intervals between meals. These remedies, with massage, were continued until June 26th, when the patient was discharged. He was able to hobble about, but he had not been greatly benefited. After his discharge his symptoms improved somewhat, so that he was able to walk up and down stairs, but the swelling of the joints remained unchanged. At the end of September he was troubled with increased pain in both hips and shoulders, but with little or none in the hands or knees. He was readmitted into the hospital on Nov. 4th in the following condition. Both wrists and all the joints of both hands were distended with effusion but without any crepitus. There appeared to be some thickening of the lower ends of the bones of the forearm, but very little bony deformity of the phalangeal joints. Both knee-joints were distended with fluid and the extremities of the bones were thickened. The shoulder-, elbow-, and ankle-joints appeared to be normal. There was great muscular atrophy of all the limbs, especially of the calves of the legs. The vertebral joints were stiff but not tender. The hands and feet were constantly moist. During the first 14 days after readmission his temperature ranged between 100° and 98·4°. He was placed on full diet and was treated with arsenic, iodides, bark, and opium, cod-liver oil, hot-air and hot-water baths, massage, &c., with varying effects on the disease, but with no marked benefit until the beginning of April. It was then decided to try the effect of continuous counter-irritation of the spine. A skiagram was taken of the left hand, of which Fig. 1 is a copy, and measurements were taken of the wrists and fingers with the following results. April 6th: right wrist, seven and five-eighths inches; joint between the first and second phalanges of the first finger, three inches; joint between the first and second phalanges of the second finger, three inches. A cast of the left hand was also taken, of which Fig. 2 is a drawing. The left wrist measured eight and a quarter inches. A blister three inches by three inches, which had been painted over with liquor epispasticus, was applied over the seventh cervical spine for 12 hours and the blistered surface was afterwards kept open for a fortnight with a daily dressing of savine ointment and was then allowed to heal. Full diet, cod-liver oil, arsenic, and tincture of bark were prescribed. On April 23rd a blister of similar size was applied over the last dorsal and first lumbar vertebræ and was kept open for a fortnight with savine ointment. The joints felt easier after the application of the blisters, but there was very little diminution in their size for the first four weeks. On May 27th the finger-joints gave the same measurements as on April 6th—viz., three inches. The left wrist now measured only seven and three-quarter inches, being half an inch less than before. The right wrist was also seven and three-quarter inches in circumference, or an eighth of an inch more than before. The limbs were now massaged every other day and the patient had a warm bath

---

[8] Pathological observations render it probable that the ganglion cells of the anterior horns exercise a controlling influence upon the nutrition of the bones and joints, while those of the posterior horns stand in a similar relation to the nutrition of the skin and its appendages.—Ross, loc. cit., vol i, p 825

FIG. 1.

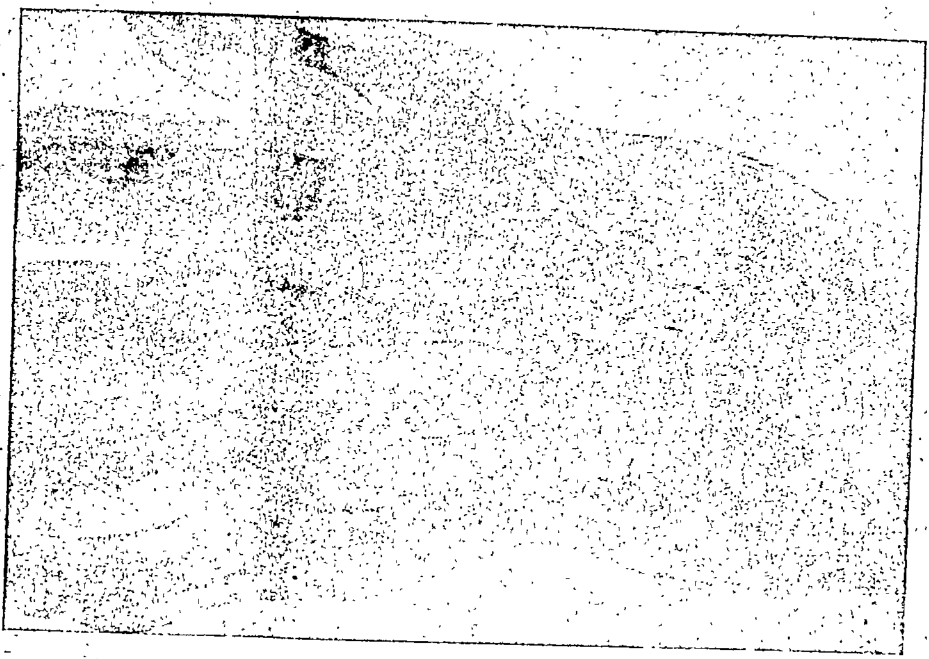

FIG. 2.

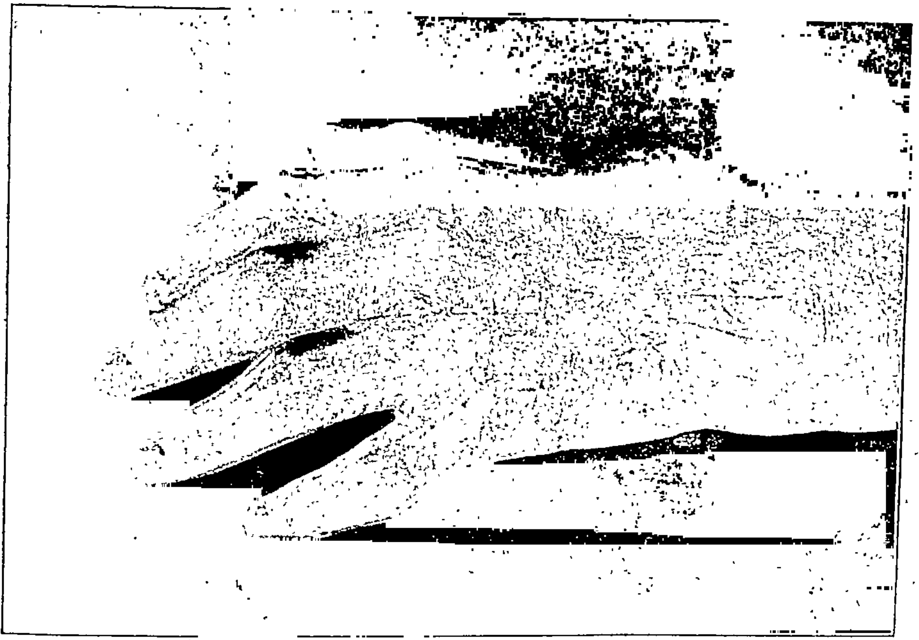

FIG. 3.

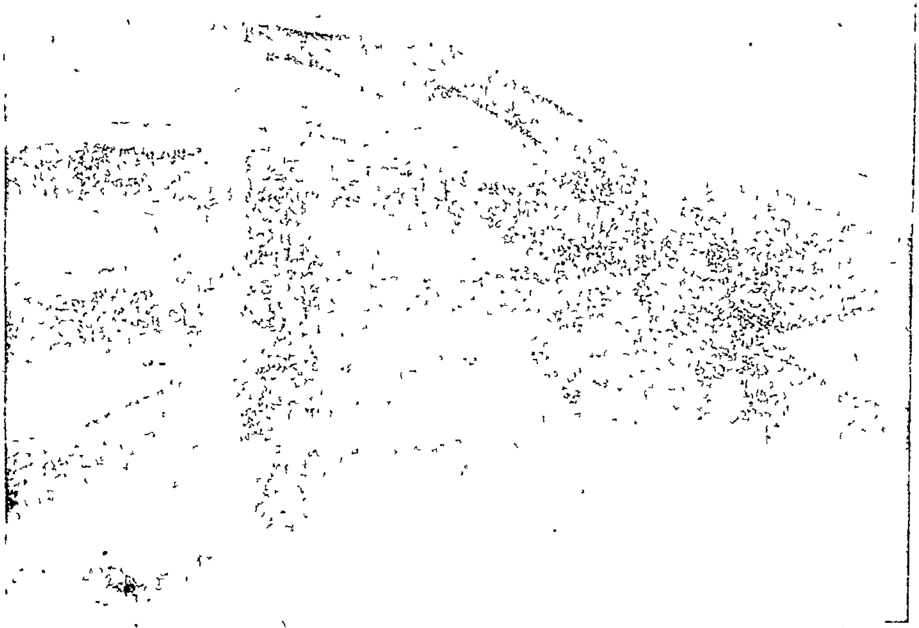

FIG 4

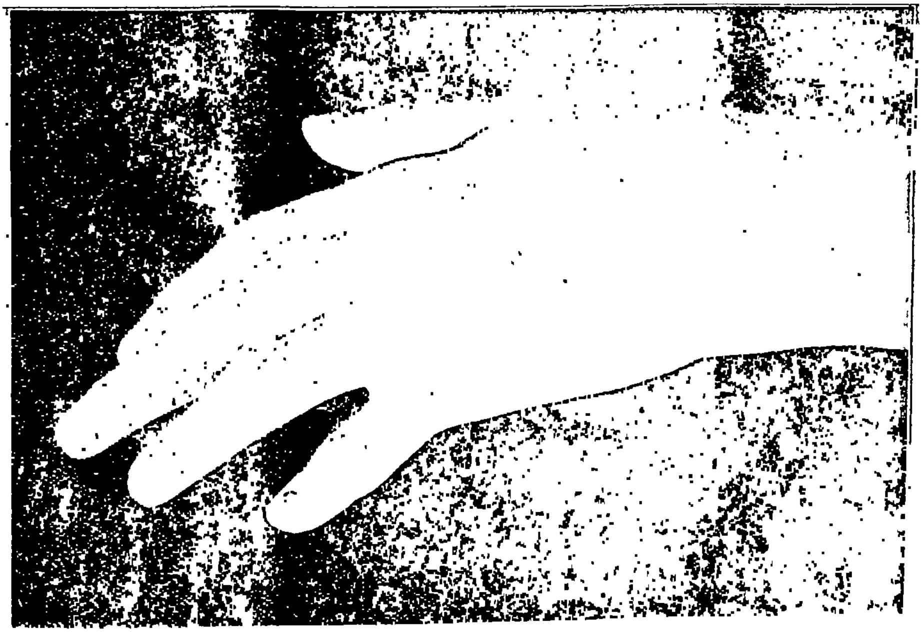


every other evening. Blisters three inches by one and a half inches on either side of the seventh cervical and last dorsal vertebræ were subsequently applied. At the end of June the joints had distinctly diminished in size, the two wrist joints each measured only seven and a half inches and the joints of the first and second fingers of the right hand had decreased to two and three quarter inches. The patient was able to walk about with the aid of a stick; the movement of the joints was limited but there was a fair range obtained by the knees and ankles. His general nutrition had greatly improved. His face was fuller and he had a healthier appearance. The limbs, though thin, had gained considerably in circumference, the calves of the legs being nearly treble their former size. Food was taken well and he complained of no pain. He remained in the hospital until August 7th, being treated with massage and baths. He now looked in good health and was able to hobble about without the aid of a stick. The measurement of the joints was the same as on the last occasion. The wrists could be easily extended, but flexion was somewhat limited, the metaçarpo-phalangeal and phalangeal joints were stiff and the grasp was feeble. There were some adhesions about the hip-joints and forced movement gave him pain. The knee-joints were still a little swollen, but they had a fair range of movement, and there was free movement of both ankles. Before he left the hospital the skiagram (Fig. 3) of the left hand and the cast (Fig. 4) of the same were taken. The changes which had taken place can be seen by comparing these with Fig. 1 and Fig. 2. On Sept. 27th the patient came to report himself at the hospital. He was able to walk better and there was freer movement of all the joints. The right and left wrists now measured only seven inches in circumference and had a fairly normal appearance. The finger-joints measured the same as on August 7th.

In this case I believe that the improvement in the patient's wretched and hopeless state was almost entirely due to the counter-irritation kept up from time to time for several days in the region of the lumbar and cervical enlargements.

The following case of a patient who was recently admitted into St. George's Hospital under the care of Dr. A. C. Latham (to whom I am indebted for the notes) is a further illustration of this mode of treatment.

CASE 2.—A widow in domestic service, aged 47 years, was admitted into St. George's Hospital on Dec. 19th, 1900, with the following history. In October, 1898, having previously had no serious illness, she suffered from influenza followed by an attack of pneumonia. In December of the same year she was seized with sudden pain in the right knee and right hand, but unattended with much swelling or heat. The left knee and left hand were shortly afterwards affected. The pain had persisted on and off up to the time of her admission into the hospital, and together with the difficulty experienced in moving her joints had prevented her from following any employment for the previous two years. Her legs had become weak and she had lost flesh during the past year. The appetite had been bad and the bowels were generally constipated. The patient was a teetotaler. There was no history of rheumatism. The catamenia had ceased three years previously. She was a spare anæmic woman and she looked older than her stated age. Both wrists were enlarged and swollen, the movements were very limited, and the outline over the carpal bones was indefinite. The metacarpo-phalangeal joints of the first fingers were swollen and there was much grating on movement The knees were both enlarged, especially the right, the enlargement being on the inner aspect. The right knee felt hot to the touch, could not be completely extended, and could only be slightly flexed. The left knee could be both extended and flexed and the patella was moveable. There was no lateral movement of either knee and grating was marked in the right knee. The temperature was normal. The patient was placed on ordinary diet and the bowels were regulated with calomel and saline aperients. On Dec. 27th a blister six inches by two and a half inches was applied to either side of the upper lumbar vertebræ and the blistered surface was kept open for a week with savine ointment. Within a week of the application of the blisters the patient complained much less of pain in the knees; the right knee was less swollen and less hot, whilst the condition of the left knee was practically normal. On Dec. 30th daily massage of the limbs and joints was ordered. On Jan. 2nd, 1901, the patient was ordered three minims of hydrochloric solution of arsenic with five minims of diluted nitro-hydrochloric acid three times a day. Her general condition was much better and the knee-joints were almost free from pain, but the wrist-joints, although improved, were still considerably swollen and rather painful, especially at night. On the 13th two blisters four inches by two inches each were applied one on either side of the lower cervical and upper dorsal vertebræ, and later the surfaces were dressed with savine ointment. The dose of arsenic was afterwards increased to five minims three times a day. On the 21st the patient's knees and wrists were much better; they could be freely moved without any pain. On the 30th she was discharged. The difference between her condition when she was first brought in a cab and assisted by her friends into the hospital and her condition when she left, able to walk without a stick and free from pain, was most striking.

In the earlier stages, then, of rheumatoid arthritis I think that continuous counter-irritation of the spine is of distinct service and that it may also be usefully employed in the acute polyarticular variety. But when the disease is advanced, the ends of the bones enlarged, and the cartilages destroyed one cannot hope to restore these to the normal condition by any counter-irritation. Such a measure would only increase the patient's discomfort Nevertheless, in chronic cases, where there are from time to time exacerbations of pain and swelling in some of the larger joints, the application of blisters to the spine is of use; and I have seen these conditions very quickly alleviated thereby and the further extension of the disease arrested.

Cambridge

A CASE IN WHICH A LARGE PYLORIC TUMOUR DISAPPEARED AFTER GASTRO-ENTEROSTOMY.

POST-MORTEM EXAMINATION ELEVEN YEARS AFTER OPERATION.

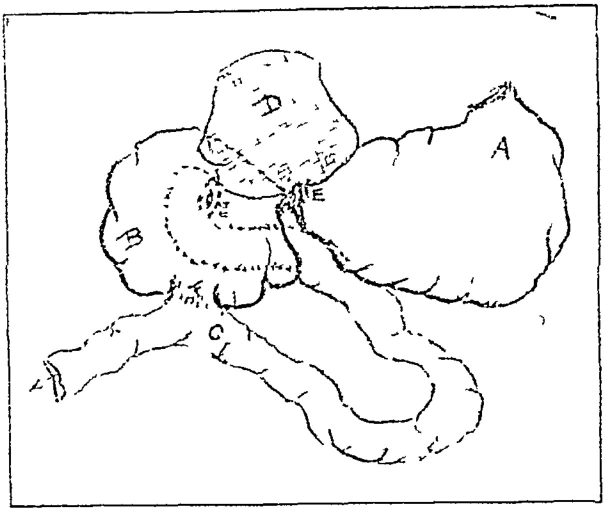
BY FRED. BOWREMAN JESSETT, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON

I VENTURE to think that this case is worthy of record inasmuch as it is one in which a tumour of the size of a small cocoanut completely occluding the pylorus, having all the naked-eye appearance of a carcinomatous growth, disappeared *after* operation, also because of the length of time the patient lived after the operation in perfect comfort.

The patient, a widow, aged 56 years, was admitted into the Cancer Hospital, Brompton, on Feb. 14th, 1890, suffering from pyloric obstruction. She had had four children, the youngest being 22 years old The menopause had occurred six years previously. The patient, who had always been delicate, had suffered from indigestion for a considerable time and had noticed a lump in her abdomen for over a year. She had been confined to her bed for about a fortnight complaining of pain in her chest and back, vomiting, flatulence, and constipation. The symptoms of indigestion had been more or less present during the last eight or nine years. There had been no hæmatemesis. The vomiting, however, increased in frequency, the pain became very acute, and she gradually continued to get worse until November, 1889, losing flesh rapidly and suffering intense pain. At this time everything she ate was vomited usually a few hours after eating. The tumour, which was situated in the epigastric region, gradually increased in size.

On her admission the tumour was found to occupy nearly the whole epigastric region situated apparently over the pylorus and extending along the anterior wall of the stomach; it was moveable and also moved on respiration. The stomach was enormously dilated, extending as low as the pubes. The patient vomited once or twice a day a brownish fermenting fluid filled with sarcinæ. She was very emaciated and weak. The urine was that of a healthy person. The stomach was washed out twice a day with a solution of salicylate of soda and nutritive enemata were given. All food given by the mouth gave great pain and was vomited shortly after. From the size and fixity of the tumour pylorectomy was negatived and it was decided to perform gastro-jejunostomy; this was done in April, 1890, by means of Senn's decalcified bone plates and the patient made an excellent recovery. At the time of this operation the tumour was carefully examined and was found to be situated at the pylorus and had all the appearances of scirrhus; it was adherent to the surrounding parts and was of the size of a small cocoa-nut.[1] The patient left the hospital some two months after the operation, and has been seen periodically until the time of her death from apoplexy in November, 1900.

At the post-mortem examination, conducted by Mr. C. N. Barton, the stomach was found to occupy practically its normal position, but there was a constriction about its centre forming a typical hour-glass contraction (see illustration), the point of constriction being firmly adherent to the left lobe of the liver. The jejunum was seen to be fixed to the anterior wall of the stomach at the seat of operation in the lower part of its distal pouch. The duodenum was of its normal calibre and apparently had continued to a certain extent in conjunction with the gastro-jejunal opening to perform its normal functions. On opening the distal pouch of the stomach the opening between it and the jejunum was found to be large enough to admit two fingers. At the constricted portion of the stomach the opening between the two pouches was very small, barely admitting one finger. The pyloric opening situated immediately behind the constriction admitted one finger with difficulty. The constricted portion was hard and firmly adherent to the left lobe of the liver. This was the only remaining sign of the large growth found at the time of the operation. The stomach walls were normal; there was no thickening. All the other organs were healthy.



Diagramatic sketch of a case of gastro-jejunostomy. Death 11 years after operation. A, Larger pouch of stomach measuring 5 × 4 inches. B, Smaller pouch, 3 × 3 inches, containing opening of pylorus. C, Jejunum. D, Left lobe of liver. E, Cicatricial band of adhesion between liver and stomach which by contraction caused division into pouches A and B. F, Site of operation (gastro-jejunostomy). G, Pylorus.

There are many points of interest in this case. First, at the time of operation the tumour had all the macroscopical appearances of a case of carcinoma of the pylorus causing obstruction. At the necropsy the pylorus was found to be patent although somewhat constricted, the mucous membrane covering it being apparently quite healthy; the pyloric orifice was situated immediately behind the constriction, which undoubtedly represented the seat of the tumour, so that possibly the tumour being in this position by its size blocked the pylorus which apparently was not implicated in the growth, and as the growth became atrophied and the obstruction removed the opening again became available for the passage of food. Secondly, it is most remarkable that this growth should have so completely disappeared leaving only a small contracted cicatrix adherent to the liver to indicate its position. There had never been any vomiting of blood or other indications to account for its disappearance. Indeed, the tumour was quite prominent and had been demonstrated on several occasions after the operation up to within about two years of the patient's death when only a slight thickening could be detected. Thirdly, although evidently food had passed by the pylorus, yet the opening between the stomach and jejunum formed the main opening for the passage of the food from the stomach into the intestine. The communication between the proximal and distal pouches of the stomach formed by the contraction and cicatrisation at the seat of the tumour was very narrow, barely admitting the index finger, and it is difficult to understand why the patient did not suffer more inconvenience than she did from the passage of food from the one pouch to the other.

A somewhat similar case is recorded by Dr. Demoulin and Dr. Tuffier.[2] It was that of a naval lieutenant, aged 32 years, who suffered from severe dyspeptic symptoms early in 1897. In 1898 a hard swelling developed in the epigastrium; all medical treatment was of no avail and the patient became emaciated. The swelling was as large as an orange. Malignant tumour was diagnosed and Dr. Demoulin operated on Dec. 1st, 1899. A soft tumour was found situated around the pylorus and the adjacent parts of the stomach and the duodenum and it felt like a fatty growth; there were no enlarged glands. The patient was so exhausted that pylorectomy was considered impracticable; Dr. Demoulin therefore performed gastro-enterostomy. The patient made a slow recovery. On the twentieth day after the operation Dr. *Demoulin palpated the epigastrium and to his surprise* the tumour could no longer be felt, its site being marked by a little thickening which vanished within ten days. In May the patient was again on active service.

The case is also of interest read in conjunction with the case of Hour-glass Stomach and Pyloric Stenosis; Gastro-enterostomy, Death, recorded by Dr. Sidney Martin and Dr. Bilton Pollard.[3]

For the outline drawing of the specimen I am indebted to Dr. C. Davis, house surgeon to the Cancer Hospital, Brompton.

Brook-street, W.

THE INFLUENCE EXERTED BY AIR UPON THE EXHIBITION OF ANÆSTHETICS.

BY GEORGE FLUX, M.D. BRUX., L.R.C.P. LOND.,
M.R C.S. ENG., L S.A.,
ANÆSTHETIST TO THE BRITISH LYING-IN HOSPITAL; CLINICAL ASSISTANT TO THE ANÆSTHETIST AT KING'S COLLEGE HOSPITAL; ASSISTANT ANÆSTHETIST TO THE DENTAL HOSPITAL OF LONDON.

AIR governs the administration of anæsthetics, by it the patient is enabled to live while he inhales the anæsthetic, and by its instrumentality the dose of the anæsthetic is determined. No manner of administration that involves the curtailment of a patient's air-supply or that fails to direct the course traversed by the air on its way to a patient can ensure either accuracy of execution or limitation of results. Any patient can be reduced to silence and the stillness necessary for surgical procedure with facile certainty, and for that matter frequently is so reduced, by the least practised of administrators. Unfortunately, the power to force a patient to inhale an anæsthetic vapour is not always associated with the practised knowledge requisite to regulate it, and the patient suffers in consequence; not only does he incur the risk of being semi-asphyxiated or totally asphyxiated, but the risk of receiving an excess of anæsthetic and, if he survives, of being grievously sick for hours.

An enormous amount of literature has been produced from time to time dealing with the very important question as to what should or should not be considered the correct dose of any particular anæsthetic. Physiologists and others have told us the effects produced upon the human body as a whole, and upon different portions of it in particular, by the presence of ascertained proportions of anæsthetics. Probably no one will deny that all patients are dissimilar, that the conditions of every operation differ, that the methods of administration differ, that each administrator employing any particular variety of so called method does so in a manner peculiar to himself, that practically the only constant factors present at *an administration are the anæsthetic and the air, and that* unless these two essential factors are under absolute and minute control no hope can ever be entertained that reliability of results will be secured or the true merits of the different anæsthetics established. A uniform dose of any particular anæsthetic is no more likely to fit every patient than is a uniform size of boot, but that is no reason why the means employed to deliver the different anæsthetics in the form of vapour should not act with uniform precision, however much it may be desirable to control and vary their rate of action. It can hardly be contended, for instance, that pouring liquid ether on to a sponge, as with Ormsby's inhaler, or A.C.E. mixture on to a sponge contained in a Rendle's mask, or chloroform *on to* a towel or "piece" of lint, are in any degree accurate methods of developing and delivering the vapours of these fluids. Neither can it be contended that the quantity of vapour produced by evaporation and inhaled by the patient are under anything like an exact control. The fluid may be poured on to the evaporating *surface in successive and carefully measured* amounts and the size of the evaporating surface controlled, but the volume of vapour available for the patient at each inspiration cannot fail to be merely conjectural. The supply *of vapour is indefinite at all times, it may be increased or* diminished knowingly or unwittingly, but the variations that do occur are variations of unequal and undetermined increments.

---

[1] THE LANCET, July 12th, 1890, p. 68.

[2] Bulletin et Mémoire de la Société de Chirurgie de Paris.

[3] Brit. Med. Jour., Dec. 8th, 1900, p. 1635.

It is not *my* intention to suggest that the allowance *of* anæsthetic vapour for each successive breath that a patient draws during an administration should be separately made the subject of an abstruse mathematical calculation and intricate *fractional measurement, as that would be manifestly* impracticable, but I do suggest the propriety of employing *methods of administration which shall not curtail a patient's* air-supply and that shall be capable of intentional variation but *incapable of indefinite action. It is highly desirable* that an administrator of an anæsthetic should be able to be conscious of the exact value of any variations that he may find it advisable to make during an administration, but it is *not essential that he should think in figures if his* arrangements are such that "more" or "less" means more or less of a definite substance. The sailor who "takes a pull" at the main sheet or "eases it off," as the case may be, does not use a *foot* rule every time he either gives more or less sheet, but the sheet is the same in length and strength throughout the voyage.

I have *said above* that air *governs the administration of* anæsthetics. *The fact that it does so may not* be apparent at first sight (I refer here to chloroform and its mixtures, to ether, and to nitrous oxide gas) and I will endeavour to show how important a part the air plays in the process. No patient can live long without air. No patient can tolerate without injury, or at least discomfort, any deprivation of his natural air-supply. No anæsthetic can be continuously given in the absence of air. The presence of air is essential to enable the anæsthetic to be efficiently employed. *Nitrous oxide gas administration well illustrates this;* this gas cannot be given without air (or oxygen) for a period longer than it takes for a patient to become asphyxiated; the same holds good with ether and with chloroform; in the case of chloroform, poisoning would probably occur as soon as, or sooner than, asphyxia. The dose inhaled of each of the above-mentioned anæsthetics is regulated *by the air-supply.* Air cannot be withheld *during* an administration without simultaneously compelling the patient to breathe an atmosphere of pure and undiluted anæsthetic vapour. Air cannot during an administration reach a patient without conveying anæsthetic vapour—the air conveys the dose; the dose conveyed depends upon the amount of anæsthetic vapour taken up by the air *en route.* The opportunity the air has of taking up vapour depends upon the route that the air has taken; if it has passed over or under the evaporating surface it will contain vapour in proportion to the *size of the evaporating area, but if it* passes through the evaporating substance it will be saturated with anæsthetic vapour.

Take, for example, the method by which chloroform is administered from a folded towel, a Skinner's frame, or a piece of lint. When held over, but not touching, a patient's face the air entering from below and all round the face-piece takes up and conveys an amount of vapour proportionate to the rate of evaporation and the size of the free evaporating surface. This can in a loose way be *depended upon to be more or* less uniform. If from any cause the mask is permitted to descend and adapt its margins to the surface of the patient's face the air passes through instead of under the evaporating area, and the whole mass of inhaled air becomes instantly charged to saturation with chloroform, an atmosphere that no living thing can withstand for more than a few seconds, as has frequently been demonstrated on the human subject. When a Rendle's *perforated mask, packed with a* sponge or other absorbent substance, is employed for giving chloroform mixed with other volatile substances the air regulates the dose in a precisely similar manner, the entering air either *picking up vapour given off from the evaporating surface* in varying but unknown proportions or becoming saturated with vapour *if drawn through the* moistened absorbent material. However, as the margins of the inhaler where in contact with the face are hard and cannot therefore fit accurately it seldom happens that all the indrawn air has the opportunity of becoming saturated unless the ingress of the air between the inhaler and the face is deliberately *prevented by the administrator; fortunately this is* a matter of some difficulty and one requiring time to accomplish. Most of these mixtures owe their fictitious safety rather to the part played by the air than to their composition. It has *not been shown in the case of any one of them that the* chloroform contained in them is less readily absorbed when inhaled, or when absorbed less potent. Were it so the utility of the chloroform in the mixture would not be obvious.

In order to ensure that the amount of anæsthetic vapour inhaled by a patient at any particular breath is the same as the administrator hopes it to be, it is necessary to employ a *system of developing and of conveying vapour* which shall not be liable to dangerous or spontaneous vagaries. In such a system it is desirable to work through the agency of some one instrument the action of which is constant. That *instrument, fortunately,* is invariably present—namely, the air. Air can only take up and convey at atmospheric pressure and at any given temperature and pressure (conditions that do not appreciably vary during any given administration) a *definite maximum* amount of any particular anæsthetic vapour, so that by controlling the amount of inspired air that is permitted to influence the supply of anæsthetic vapour the proportion of anæsthetic present in the air at each inspiration can be gently and evenly raised or lowered as occasion requires.

As I said before, it is the air which ultimately determines the amount of anæsthetic inhaled, but—and herein lies the difference between the methods usually employed and the system which I now advocate—in the former the air is excluded from, or admitted to, the patient without regard to the influence exerted by the air upon the magnitude of the dose of the anæsthetic employed; in the latter the air is not excluded from the patient, and its natural properties are purposely employed *to govern and limit the output of* anæsthetic vapour, and the anæsthetist manages the anæsthetic by means of the air rather than in defiance of it. Until it is recognised that during the administration of any anæsthetic every alteration that occurs to a patient's air-supply produces simultaneous alteration in the dose of anæsthetic inhaled the dangers that arise from unsuspected variations are likely to continue. He who *administers* an anæsthetic has two widely differing tasks to perform. Firstly, he has to exercise his judgment both as to the limited effects he wishes to *produce* upon the patient by the anæsthetic and as to the variations in dosage requisite to keep his patient in a satisfactory condition; and secondly, he has to act up *to* his judgment, and, therefore, unless he is in a position to dispense his anæsthetic vapour with accuracy his performance must of *necessity be uncertain.* The dangers that do arise from unsuspected or uncontrolled variations are not rendered *less frequent* by the very prevalent custom of regulating the dose according to the effects produced (in *contra-distinction to regulating* the *effects* by the dose). This custom has, especially when the equipment which is employed to exhibit the anæsthetic vapour is in the least degree indefinite in its action, the great drawback that very undesirable effects are liable to be established prior to their *becoming apparent to the* administrator whose subsequent efforts to regulate his dose may be too late. There is another drawback to this *custom—namely, that* unpractised administrators are prone to give their patients the most that they can stand short of their exhibiting actual symptoms of poisoning, rather than to restrict their administration to the limits of efficiency—a proceeding requiring the exercise of considerably greater judgment.

The system of administering anæsthetics by means of the air is simple and has the advantage that it is equally applicable to all anæsthetics. It consists, not in attempting to control the output of vapour by varying the copiousness of the source of supply, which under this system is a matter of indifference, but in regulating the amount of fresh air that is permitted to take up fresh anæsthetic vapour at each inspiration, this amount being, although definite in composition, variable in quantity at discretion, and it becomes added to the fresh air which completes the inspiratory volume. The essential points in respect of the equipment employed for utilising this system are that it should be absolutely incapable of spontaneous alteration in either shape or condition—of being varied in action by the patient—or of automatic action. Specially constructed apparatus is not necessary when these conditions are present. I should like to emphasise the fact that administration by means of air is only a system for providing a patient with the vapour in a definite manner; the amount administered must, as in the case of all therapeutic agents, be a question entirely of judgment; but of one thing I am certain, and that is that the system cannot, until nature changes the property of air, play its employer false. Personally I use, when carrying out this system in its entirety, apparatus of my own devising—namely, an inhaler for chloroform, an open apparatus for nitrous oxide gas, a special form of stopcock for use with nitrous oxide or for use when employing Clover's ether inhaler, whether with or without gas. These were made originally for me by Mr. J. H. Montague of 101, New Bond-street, W.

Old Burlington-street, W.

THREE CASES OF ACUTE ASCENDING PARALYSIS.

By T. A. GREEN, M.D. Edin.

Acute ascending paralysis is a condition of great interest, not only because of its comparative rarity, but also on account of the very diverse opinions which have been held as to its causation. The first published cases of the disease (10 in number) were contributed by Landry in 1859—hence it often goes by the name of Landry's paralysis; and since then many other examples of the disease have been continuously put on record. The most extensive contribution to the literature of the disease in this country was made by the late Professor James Ross of Manchester who, in 1889, in a series of articles on "Peripheral Neuritis" collected and discussed 93 cases in the *Medical Chronicle*, vols. x. and xi. In February, 1896, a paper on "Idiopathic Acute Ascending Paralysis," by Dr. Reynolds, appeared in the same journal, and several cases have been narrated in the various medical magazines. It has been my fortune to see three cases of the disease in my own practice and to these I am able to add a fourth—a most interesting case—which occurred in the practice of a friend. I propose to give an account of three of these cases and I trust at some future time to be able to discuss the condition in order to bring out some points which I think worthy of note. In order to do this I shall take full advantage of the series of cases collected by Ross which will be found in tabulated form in vol. x. of the *Medical Chronicle*, p. 358. A somewhat different explanation of the disease to that advocated by Ross can, I think, be given.

My cases are as follows.

Case 1.—The patient was an unmarried girl, aged 19 years, living at home with her parents. Her father and mother were alive. The father suffered from chronic bronchitis. The brothers and the sister of the patient were healthy; one aunt had had "swelling in the neck and went off in a decline." Until two and a half years previously there was nothing of importance—no rheumatism or syphilis. For two and a half years she had suffered from Graves's disease in which all the usual symptoms of that condition had been displayed. During this time her menstrual periods became irregular and finally they ceased five months before the present illness. Subsequently to their cessation, however, she had suffered from periodical attacks of epistaxis. On June 30th, 1894, the patient came to consult me and complained of general weakness, severe headache, sickness, and constipation; in addition she was suffering from one of her attacks of epistaxis. On inquiry I found that she had been under treatment at the local infirmary for some months for her "goitre." This had been progressing favourably and on her last visit there (June 21st), nine days previously, she was very much better. Hurrying off to the station, however, she missed her train and received a severe chill and had felt ill ever since.

On examination the symptoms of goitre were well marked. The heart was enlarged and there was a systolic murmur at the base. In the lungs there was chronic bronchitis with purulent sputum but no consolidation. On July 4th I was called in to see the patient and I found that the general weakness was increasing, especially in the lower limbs. She was sitting in a chair, but was quite unable to stand or to walk by herself. Epistaxis still continued at intervals, as did also the sickness. She complained of violent pains striking from each side of the neck down into the shoulders and the arms, worse on the left side. Vision was good; the pupils were equally dilated and reacted to light. The pulse was 120 and weak and the temperature was 99°F. The sickness and epistaxis gradually became relieved, but the muscular weakness still progressed and attacked the upper limbs—first the muscles of the shoulder and the upper arms, then the muscles of the forearm—and she was obliged to take to her bed. On July 7th the neuralgic pains returned at intervals and on this day the patient had a sharp attack of palpitation and dyspnœa which lasted about 10 minutes and then passed off, leaving her in a very exhausted condition. She also complained that her eyesight had gone and the eyeballs seemed more prominent. On the next morning (July 8th) I found that she had passed a very restless night with delirium and was in a very exhausted state. The lower limbs were completely paralysed and she was lying propped up in bed. The upper arms were quite helpless, but she could with difficulty raise the forearms off the bed. The grasp of the hand was very feeble. Sensation was unimpaired, superficial reflexes could be elicited, but ankle-clonus and knee-jerk were absent; there was no wasting of the muscles. Her eyesight had improved, but from this time her power of vision varied from day to day. Attacks of dyspnœa came on three or four times a day. From this time she continued to get weaker; the muscles of the trunk became gradually paralysed and by July 15th she could only swallow liquid nourishment with difficulty. Her tongue became dry and brown and sordes began to collect on the teeth. Delirium was now almost constant. On the night of the 15th she complained of pain in the chest and her temperature was 100°. Next morning I found that she had had a very bad night, with restlessness, pain in the chest, and attacks of dyspnœa. Her breathing was difficult and on auscultation the action of the heart was found to be very laboured and galloping. The temperature was 101°. She gradually became worse and died at 11.30 A.M. from paralysis of respiration. The sphincters acted normally until just before death when there was some incontinence of urine. There was no post-mortem examination.

Case 2.—Dr. J. Scott Taggart, who was assisting me at the time, greatly helped with the notes of this case. The patient previously to this illness had been a strong, healthy man. His age was 23 years and he was married and had one child. He was a quarryman by occupation, was well known as a football player, and was a very temperate man. His previous illnesses had been restricted to obstinate constipation and slight accidents at football. One of the latter had happened four months before the present illness, when he received a kick on one shin, and a troublesome little ulcer, deeply injected and never larger than a shilling, formed and did not heal for five or six weeks. On May 20th, 1895, he was quite well, but on the following morning he began to suffer from pain in the calves of the legs. These pains became so severe that he gave up work at noon and then the pains extended through his legs and back. On the next day (May 22nd) he was worse and he sent for me. He now complained of pain in his head (both back and front), in his back, and in the muscles of his thighs and legs.

On examination the tongue was found to be coated with thick white fur, the mouth was sore inside, the teeth were bad especially on the left side, and his appetite was bad. The heart and lungs were sound. The temperature was normal and the pulse was 60 per minute. There were slight redness of the conjunctiva and watering of the eyes. The pupils reacted to light and accommodation. There was no numbness or disturbance of ordinary sensation and no paralysis or paresis. The painful parts were not tender to pressure. On the 23rd the pain had left the back and was localised in the back of the thighs and in the calves. The temperature was normal and the pulse was 60 The eyes were still injected, but there was no pain or photophobia. A herpetic eruption had appeared on the lips, the mouth was still sore, and the tongue was furred. On the 24th the patient was quite free from pain and headache. The temperature was normal and the pulse was 60. He however complained of sleeplessness. He got up at noon and dressed, but felt so weak that in two or three hours he went back to bed. The appetite was improved. On the 25th the patient was in bed, suffering no pain but feeling very weak. He could move his legs and toes, also his arms and hands, and his grasp was fairly good—a little stronger on the right than on the left side. He was unable to stand alone and complained of numbness in his hands and feet He could distinguish between the head and point of a pin all over his upper and lower extremities. He was perspiring freely. On the 27th I found the patient very weak but his appetite was good. He was lying on his back and was unable to raise his lower extremities from the bed though the contraction of the muscles could be seen and felt. He could slightly move his foot, but not his toes. The muscles of the thigh were much more powerful than were those below the knee; no tendon or skin reflexes could be elicited on either side in the lower extremities. The upper limbs were very weak. He could only just move his fingers; he could close his hand but his grasp was extremely feeble (practically absent). The muscles moving the wrist were a little stronger; the muscles of the arms were fairly strong and those of the shoulder and neck were in good condition. The sphincters were normal; perspiration was still profuse. On the 28th the patient was much the same as on the previous day but had developed facial paralysis on the left side. He said that his mouth became drawn on the afternoon of the previous day. He had had a sleepless night; the pulse and the breathing were good. The temperature was 99° F. He was rather troubled with some thick sticky mucus in his throat, which was with difficulty coughed up. On the 29th at 1.30 A.M. the patient was taken suddenly worse He became delirious and slightly cyanosed. The temperature was 99.4° and the pulse was 114. He perspired freely and was troubled with the mucus in his throat, which, however, was not large in quantity. His delusions during his delirium seemed to have some connexion with his paralysis, seeing that he called upon his friends to save him from sinking through the bed or to deliver him from people who were tying him down or who were suffocating him Under treatment he rallied and two hours afterwards he went to sleep. He was seen again at 10.30 A.M. and had then had three or four hours' sleep. He had had a good breakfast. His limbs were quite powerless. The pulse was 110 and full. The diaphragm was paralysed and the breathing was intercostal in type. There was slight cyanosis and the mucus in the throat was still troubling him. At 3.30 P.M. he was again taken suddenly worse and in spite of all treatment he did not improve He became extremely cyanosed and quite wet with perspiration The pulse was 110, full and regular, and the respirations were 30 per minute There was a large quantity of thick tenacious mucus in his throat and his extremely weak efforts to get it up exhausted him very much; its removal afforded temporary relief, but it soon accumulated again. The cyanosis gradually increased, then came failure of respiration, and finally failure of the pulse and death at about 4 P.M. Unfortunately I was unable to get a post-mortem examination and there were no electrical tests.

CASE 3.—The patient was a male child, aged three years and 10 months. There was no particular family or personal history. On June 2nd, 1900, I was sent for to see the child and found him suffering from a mild though undoubted attack of diphtheria The membrane was confined to both tonsils and the upper pharynx and did not spread to the larynx The case was not a severe one and the temperature was never above 101° F. There was little swelling of the glands of the neck. Antitoxin was not used. The throat was swabbed out twice daily with antiseptics—at first with a solution of izal (1 in 50) and later with carbolic glycerine—and by June 13th to all appearances the throat was in a normal condition. On the 16th difficulty of swallowing supervened with paralysis of the muscles of the soft palate and regurgitation of fluids through the nose. There were also weakness of the lower limbs and inability to stand without assistance The upper limbs, however, were fairly good; sensation was normal and there was no active wasting of the muscles Liquor strychninæ hydrochloratis in one minim doses was administered every four hours, but the child showed no signs of improvement He continued in this state until July 3rd when it was noticed that the head was drawn to the right side from paralysis of the muscles of the left side of the neck. There were also "rattling" in the throat and increased difficulty of swallowing from paralysis of the lower pharyngeal muscles On the 7th there was marked increase of paralysis of all the muscles of the body. The child was lying on his back and it was with difficulty that he moved either legs or arms. The head was not so much drawn to the right side owing to commencing paralysis of the muscles of the right side of the neck. On the 10th the breathing had become costal in type. There were paralysis of the diaphragm, complete paralysis of the lower limbs, and only very slight movement in the upper limbs The knee-jerk and the superficial reflexes had disappeared. The eye reflexes were normal and the child was conscious until he died in the afternoon from failure of respiration. After June 13th the temperature continued normal and there was no active wasting of muscles all through the illness. Sensation was normal and there was no incontinence of urine or fæces

LARYNGEAL DIPHTHERIA (?).

BY A. DE WINTER BAKER, M.R.C.S. ENG., L.R.C.P. LOND.

THE fatal case of laryngeal diphtheria reported by Dr. G. J. Maguire in THE LANCET of March 23rd, p. 854, induces me to send you a short note of a case which has recently occurred in my practice.

The patient was a boy, four years of age, of a highly nervous and excitable temperament, whom I had attended about a year before for a bad cold and slight enlargement of the tonsils. On the present occasion I was called to him one evening and found him suffering from a croupy cough. The tonsils and fauces were slightly red and inflamed, but there was nothing like any membrane to be seen, and his temperature was only 99° F., so that, judging from his former illness and bearing in mind that he had some chronic enlargement of the tonsils, I believed the case to be one of simple catarrh about the glottis and told the friends that they might hope for a speedy improvement from the use of suitable remedial measures. On visiting the patient on the next morning I found him up and dressed the croupy sound having quite gone and the temperature being normal, and he was altogether so much better that I did not intend to visit him again until the day after next. However, in the evening of the same day I was again sent for and I found him with stridulous breathing and general signs of obstruction of the larynx. The temperature was only 99°. No membrane could be seen on the fauces or tonsils, and as it was exceedingly difficult to get a view of the throat owing to the refractoriness of the patient I judged it wiser not to introduce a swab for bacteriological examination as I should have liked to do On the same evening Dr. O. J. Harrison saw him in consultation with me, and we decided to inject anti-diphtheritic serum. However, owing to the syringe breaking this was not done at the time. On the next morning the breathing was better, but the temperature rose steadily through the day, reaching 103° in the afternoon, when it began to fall again, and it was 100° at night There were harsh râles over both lungs. A fresh syringe having been procured 2000 units of serum were injected at night in spite of the patient being evidently easier and better. On the next morning the temperature had fallen to 99° and the patient was better in every way, and from that time he made an uninterrupted recovery.

Whether this was a case of diphtheria or not and whether the improvement was due to the serum injection I am unable to say positively. No membrane was coughed up or seen at any time. Doubtless, as Dr. Maguire says, there are cases of mild diphtheria that are not recognised, but the lesson to be learned from these mild cases is the value of serum injection. As far as I am aware it does no harm, and I shall certainly resort to it again in any doubtful case. I think it is possible that had it been used in Dr. Maguire's case the result would have been different.

Northumberland-avenue, W.C.

CARCINOMA OF THE PROLAPSED UTERUS.

By HERBERT SNOW, M.D. LOND.,

SENIOR ACTING SURGEON TO THE CANCER HOSPITAL, BROMPTON.

A WOMAN, aged 73 years, the wife of an agricultural labourer, was admitted to the Cancer Hospital, Brompton, on Jan. 16th, 1901, with carcinoma of the prolapsed uterus. There was no family history of cancer. The uterus had become procident at the climacteric period—i.e., about 28 years previously—and she gravely stated that this had been brought on by her husband rubbing her back for the common lumbar pains. She had since gone about as usual, wearing only a diaper, and no pessary or other support had ever been resorted to. The cancerous development (cervical) was said to have commenced a year before. As the duration of malignant disease in the female is almost invariably much understated, one of about twice that length was inferred from the objective phenomena. Above the growth was a considerable margin of healthy vaginal mucosa. The parts were freely mobile. Unfortunately, however, there were signs of extensive implication of the bladder. The urine was copiously laden with pus and albumin. The patient was very senile and hence the idea of operative removal had to be abandoned. She had pain on micturition but at no other time, and while she was kept in bed she had no suffering whatever. She still remains in hospital.

Carcinoma, cervical or otherwise, of the procident uterus seems to be a singularly rare event; whereas it might have been expected to be common, from the exposure to friction. I have not met with a case before, nor have any of my medical friends to whom this has been mentioned. Presumably the rational explanation is that the existence of the disability induces care of the exposed parts with concomitant cleanliness and health. Ordinarily, too, a pessary is worn. The disease in this case seems to be a result of the neglect of all such precautions.

Gloucester-place, Portman-square, W.

A MODIFICATION OF THE ROMANOWSKI-RUGE METHOD OF STAINING THE PLASMODIUM OF MALARIA AND OTHER PROTOZOA.

BY W. HANNA, M.B. R.U.I., D.P.H. CANTAB.

THE following account of a modification of Romanowski's method will be found in the *Russian Archives of Pathology, Clinical Medicine, and Bacteriology*, vol. x., part 4, where Dr. N. Berestneff describes an exceedingly convenient and rapid method of staining malaria plasmodia. It has been used with great success in this laboratory and deserves to be widely known in scientific institutions in England. The following is the method of preparation. A 1 per cent. aqueous solution of methylene blue (med. puriss. Höchst) containing 0 3 per cent. of carbonate of soda, is heated for three hours on a water bath and filtered. One cubic centimetre of this solution is mixed with 1·5 cubic centimetres of a 1 per cent. aqueous solution of methylene blue and to this mixture are added five cubic centimetres of a 1 per cent. aqueous solution of eosine (extra BA Höchst). Old preparations of semilunar bodies and halteridium Danielewskii ought to be stained in this mixture for from 15 to 20 hours at laboratory temperature. For young forms it is sufficient to stain for from 15 to 20 minutes without heat, followed by gentle heating for from 15 to 20 minutes until steam rises. To decolourise the red cells, which are blue after this staining, the preparation is put for from two to five seconds in the following mixture:—10 cubic centimetres of methylene blue, one per cent., 200 cubic centimetres of distilled water, and 0 25 cubic centimetre of acetic acid. The preparations are washed in water and dried with blotting-paper, and they are then dipped for from five to 20 seconds in absolute alcohol to dissolve off any residual stain and finally washed in water. Fresh preparations of blood containing plasmodia fixed with absolute alcohol are stained in this mixture diluted with from two to four volumes of water for five minutes without heat, followed by gentle heating for from five to 10 minutes. Blood containing trypanosoma and slides of the intestinal contents of guinea-pigs having trichomonas fixed with absolute alcohol or sublimate, are stained with this mixture undiluted or diluted with two volumes of water, as for plasmodia. The flagella are stained a violet-red and it may be seen (in trypanosoma) that they have a nucleus; the same may be said regarding trichomonas. The chromatin of plasmodia and the other protozoa in question is stained by this method a bright red violet, the protoplasm blue, the leucocytic nuclei and Bizzozero's plates like the chromatin of the protozoa, neutrophile granules are rose, eosinophilous cells are purple, whilst the red corpuscles are of a delicate rose colour. Dr. Berestneff working in Bombay has informed us that he has slightly modified the above for tropical climates. He adds the stains in the following order and well mixed: Soda methylene blue 1 per cent. diluted with equal parts of water, 0·5 cubic centimetre; methylene blue 1 per cent. diluted with equal parts of water, 1·5 cubic centimetres; and eosine 1 in 2000, 5·0 cubic centimetres. He informs us that the best results are obtained with fresh preparations of halteridium and malaria by at once floating the dish containing the mixture and preparations for from five to 10 minutes upon the surface of water raised to 55° C. The above method has been tried here with excellent results.

ST. GEORGE'S HOSPITAL.

A CASE OF FRACTURE DISLOCATION OF THE CERVICAL SPINE COMPLICATED BY FRACTURE OF THE SKULL.

(Under the care of Mr. W. H. BENNETT.)

THE value of traction in replacing dislocation of the cervical spine is sometimes very marked, for often the displaced vertebra gives rise to paralysis merely by pressure, the tough dura mater saving the cord from laceration. The slowness of return of movement and sensation after removal of the pressure is probably to be attributed to the presence of œdema at the injured spot. A little blood also may have been extravasated and some hours or days may elapse before this can be absorbed. The unfortunate cerebral complication in the following case prevented a recovery which the skill of the treatment deserved. More than 18 hours elapsed between the occurrence of the injury and the onset of the coma. This is an exceptionally long interval of consciouness in a case of meningeal hæmorrhage, for the coma usually comes on within an hour or two. For the notes of the case we are indebted to Mr. P. L. Mummery, F.R.C.S. Eng., house surgeon.

A plumber's assistant, aged 25 years, was taken into St. George's Hospital at 6.30 P.M. on Jan. 16th, 1901, having just fallen from the roof of a house (a distance of about 30 feet) on to a grass lawn. He was said to have been quite conscious when he was picked up after the accident. On admission he described the accident and complained of pain in the neck and jaw. His head was turned towards the left side with the chin pointing forwards and was fixed in that position; on examining the cervical spine some displacement of the sixth spine could be felt There were complete paralysis and loss of sensation below the level of the second rib, with loss of sensation and paralysis of both arms. *Respiration was entirely diaphragmatic.* The knee-jerks were absent, but the plantar reflex was well marked. There was priapism. On the left side of the face there was a deep depression about three inches long over the malar bone and involving the left orbit, the whole surface of which was severely burnt, this being due to his having fallen on to a hot soldering-iron which was in his hand at the time of the accident. A diagnosis of dislocation with pressure on the cord at the level of the sixth cervical vertebra was made, and it was decided to make an immediate attempt to reduce it.

The patient having been placed flat on his back traction was made by pulling on the lower jaw and occiput, counter extension being maintained from the ankles by an assistant while another assistant fixed the shoulders. After pulling for some time something was felt to slip with a distinct click, followed immediately by relief of pain and free mobility of the head. No anæsthetic was administered, and the *patient did not complain of pain during manipulation.* At 8 P.M. he could move both arms and sensation in them had returned; he was quite comfortable and slept for some hours. At 6 A.M. on Jan. 17th he vomited at intervals for two hours. His abdomen was distended and his breathing was very laboured in consequence. Two large enemata of olive oil were given to clear the rectum of hardened fæces, the long rectal tube was then passed, and manual pressure was made on the abdomen. In this way a large quantity of flatus was expressed and the distension was relieved. An injection of morphia (one-third of a grain) was administered and was followed by marked improvement in the breathing and cessation of vomiting. At 10 A M. he was much better; the paraplegia and loss of sensation, however, remained the same. The knee-jerks were still absent; some twitching of the legs and left hand was noticed. At about 1 P.M. he began to get rather drowsy and his temperature rose to 103° F. The right pupil was noticed to be rather small; the left, owing to the burn, could not be seen. Priapism had disappeared. At 4 P.M. he was conscious but very drowsy. He gradually became more drowsy and his breathing stertorous; at 7 P M, he died.

Necropsy.—At the post mortem examination an extensive fissured fracture of the vault and base of the skull was found, with a large blood-clot due to rupture of the left middle meningeal artery pressing on the left cerebral cortex On examining the spine it was found that the body of the sixth vertebra was fractured and there was evidence of a recent dislocation at this level. There was no displacement of the spine at the time of the examination and the cord itself appeared to be uninjured There was no hæmorrhage either between the membranes or in the cord itself. All the other organs were normal

Remarks by Mr MUMMERY —From the necropsy it is obvious that the patient died from compression of the brain and not from the spinal injury, though it was impossible to diagnose the compression during life owing to the other injuries. If it had not been for the head injury it seems probable that complete recovery would have followed, as there was no gross lesion of the cord and all pressure had been relieved by the reduction of the dislocation. A point of interest in this case was the amount of force necessary to reduce the dislocation—the force required was very considerable. The case also shows that immediate recovery from paralysis must not be expected after reduction of the deformity. The spinal cord seems to require a certain time to recover after being subjected to pressure. This is even more noticeable in those cases in which laminectomy is done for the relief of pressure, complete recovery sometimes following weeks or even months after the operation. One of the most difficult things in treating these cases is to prevent distension of the abdomen. The most effective means appears to be the use of the long tube and pressure on the abdomen combined with the use of oil enemas.

STANLEY HOSPITAL, LIVERPOOL.

A CASE OF COMA FROM THE APPLICATION OF CARBOLIC COMPRESSES TO THE UNBROKEN SKIN.

(Under the care of Mr. D. DOUGLAS CRAWFORD.)

CARBOLIC acid is absorbed freely by the unbroken skin and in most cases merely darkening of the urine occurs, but if the area to which the drug is applied be large, or the solution strong, severe symptoms are very liable to follow. Coma, with great acceleration of pulse and respiration, is not very rarely observed, and it may lead to a fatal issue, but if the cause of the coma is recognised, and the application is discontinued, recovery nearly always ensues. A case has been recorded,[1] where in error "pure carbolic acid" was used instead of carbolic oil for cleansing the scalp of a child. Within five minutes consciousness was lost and the child remained comatose for five hours. In this case the rapid onset of symptoms was due to the great strength of the application. Litton-Forbes in 1880[2] drew attention to coma as a result of carbolic acid dressings. At the present time antiseptic dressings containing carbolic acid are much less frequently employed than they were in the early days of antiseptic surgery and therefore these untoward results are less frequently noticed, consequently it is important that cases like the following should be recorded, for the dependence of the coma on the carbolic acid applications might fail to be recognised. For the notes of the case we are indebted to Dr. R. G. Henderson, late senior house surgeon.

A girl, aged four years, was admitted into the Stanley Hospital, Liverpool, under the care of Mr. Douglas-Crawford, on Sept. 8th, 1899, suffering from severe double genu valgum. She was a well grown child with thin delicate skin, was somewhat poorly nourished, and was of a rather nervous disposition. On the 13th it was proposed to perform Macewen's osteotomy on both legs. At 6 A.M. compresses of carbolic lotion (1 in 40) were applied to both legs, reaching from above the ankle to about the middle of the thigh. At 10 A M these were removed, the child had a bath, and the legs were scrubbed with oil of turpentine. At about 10 50 A.M. compresses of the same strength were reapplied At 11 A M. the child was apparently quite well and had some milk to drink. At 11.30 A M. Dr. Henderson visited the patient with the object of fitting suitable splints for use after the operation. The child was then asleep She was turned on to one side while the splints were being fitted, but during the manipulation she did not wake up It was observed that she looked rather pale and that the limbs were somewhat limp, but Dr. Henderson regarded her at the time as enjoying a very sound sleep and did not allow her to be awakened. At 1.30 P.M. he sent for the patient to be taken down to the theatre and was then informed that the child looked very ill and could not be awakened. He found that the patient was almost completely comatose, but on sharp stimulation, as by pinching or rubbing the ribs with the knuckle, she would respond slightly by raising the arms or turning the head. The skin was ghastly pale, cold, and clammy. There was marked muscular relaxation, the limbs dropping quite limp when lifted. The knee-jerks were absent. On touching the cornea there was a very slight response of the lids. The pupils were normal in size or slightly dilated, equal, and reacted well to light The lids were not quite closed and were subject to a slight spasmodic winking movement. The temperature could not be got in the axilla, the mercury refusing to rise but in the rectum 98 6°F. were registered. The pulse ranged from 170 to 180 and was small, but at this time it was quite countable at the wrist. The heart-sounds were clear and nothing abnormal was noted. The position of the apex-beat was not definitely localised. The respirations numbered 36 per minute and were deep and regular, but there was no stertor. At 2 P M. the child was in practically the same condition except that the pulse was running at 160 or more and could not be distinctly counted at the wrist. Dr Henderson was at first much puzzled as to the cause of those symptoms. The urine had been examined in the morning and found to be normal. The heart and lungs were normal, and the child had had nothing to eat or to drink for hours It then occurred to him that the carbolic dressings might be the cause. These were at once removed and the legs were well washed. A specimen of urine which was drawn off by the catheter was of a light-greenish colour and of specific gravity 1022 and contained no albumin or sugar. Brandy was administered, hot bottles were applied, and a dose of the hospital white mixture (magnes sulph. and carb. with peppermint water) was given. At 2 45 P.M the pulse was rather worse, being hardly perceptible at the wrist; the coma was, however, somewhat less profound. The patient would open her eyes widely if sharply stimulated. Brandy and white mixture were again given. At 4.15 P.M. she vomited, bringing up the white mixture that had been taken previously. At 4 40 P.M. the pulse was better (142), muscular tone was returning, and she was more conscious. The pupils were more dilated and reacted as before. At 6 P.M. the pulse had fallen to 120. The respirations were 32. She had been perspiring a great deal. At 7.15 P.M. she passed spontaneously five ounces of urine which was green in colour, darker than the first specimen, of specific gravity 1047, and contained no albumin or sugar. At 10 P.M. the temperature was 97° in the axilla, the pulse was 130, and the respirations were 24. An hour later she passed four and a half ounces of urine similar to the last specimen, but the specific gravity was only 1025. On the following morning it was reported that the patient had slept well and had taken milk well. She now seemed to be all right except for some pallor and rapidity of the pulse. These symptoms improved in the next few days, during which time the urine continued to show a gradually diminishing excretion of carbolic acid.

[1] THE LANCET, March 2nd, 1895, p. 543.
[2] London Medical Record, 1880, p. 173.

Remarks by Dr. HENDERSON.—The occurrence of coma from the application of carbolic dressings to the skin prior to operation must be extremely rare if we are to judge from the few cases that have been recorded and when we think of the great number of surgical operation cases that are so prepared. I consider, therefore, that the above case is worthy of record In regard to the sequence of events in this case it is to be observed that the 1 in 40 carbolic compresses had been applied for four hours without producing any symptom, that the limbs were then scrubbed with turpentine and the compresses were re-applied, and that 40 minutes later the child was found in an unnaturally deep sleep which continued for two hours, when she was found in the state of collapse and coma described. It seems to me, therefore, that the absorption took place chiefly from the second compress and that the cleansing by oil of turpentine assisted the process partly no doubt from clearing the pores of the skin from fatty matter and probably also from acting as a solvent and vehicle for the carbolic poison. The skin of both legs was absolutely unbroken and when the compresses were removed there was no sign of irritation such as one frequently sees from the use of stronger lotions of 1 in 20. Other points to be noted are that vomiting occurred only once, and that when the patient was coming round and that there was no rise of the temperature above the normal.

I have been able to find records of only three cases similar to the above. Mr. Clement Lucas and Mr. Arbuthnot Lane record two cases occurring at Guy's Hospital[1] and Mr. Lucas reports a second case.[2] Mr. Lucas's first case was that of a boy, aged 15 years, who was the subject of old bone disease of the hip. There were three small sinuses present. A compress of 1 in 20 carbolic acid was applied at noon. He was very sick in the evening and at 2 20 A.M. was found in a comatose condition, the pulse being 200 per minute and very feeble, the breathing stertorous and perspiration profuse. There was no corneal reflex and the pupils were moderately smaller and reacted to light. The coma gradually passed off, but the patient was stupid all the next day, the temperature rising to 103 4° in the evening. He gradually resumed his normal condition in a few days. An interesting feature about the case was that after his recovery carbolic compresses were re applied, to be followed by a train of symptoms similar to those before.

Mr. Lane's case occurred in a boy, aged six and a half years, who had a tumour in the right iliac *fossa*. Here the skin was absolutely unbroken. An hour and 10 minutes after the application of a 1 in 20 compress he was found pale, collapsed, and comatose; the pulse was 130, weak and intermittent; there was marked dyspnœa; the respirations were 72 and the temperature was 97°. Ether, atropine, and brandy were administered. Mr. Lane describes trembling of the limbs and eyelids, as well as the active reaction of the pupil to light, combined with absence of the corneal reflex—features which were well marked in the present case. Gradual improvement took place and six hours from the time symptoms were first noted the child was quite rational, but was sick at intervals for the next 24 hours.

Mr. Lucas's second case was that of a girl, aged five years, with rickety deformity of the tibia. Two hours after the application of a 1 in 20 carbolic compress she was pale and sleepy and about an hour later she was found comatose, though not absolutely so, and with very dull reflexes, clammy sweat, and very rapid feeble pulse. Here the heart was definitely found to be dilated. The conjunctival reflex was not quite lost, the pupils were dilated and almost fixed, becoming contracted later. The patient gradually improved, the coma having passed off in about six hours, leaving her in a stupid condition. There was no rise of the temperature above the normal.

It will be observed that in these three cases the lotion used was the strong 1 in 20. In the present case it was only 1 in 40. In all instances the cardinal symptoms have been alike—pallor and drowsiness (not always observed) leading to coma, with deep or rapid stertorous breathing and an alarmingly rapid and feeble pulse. Profuse perspiration and vomiting were always present. The reflexes were greatly dulled or abolished with the somewhat remarkable exception of the pupil reaction to light, which remains, although the cornea is quite insensitive. Prognosis is good, as in all these cases recovery has ensued in spite of the alarming symptoms. In addition to stimulants and warmth I should, in a case of prolonged coma from this cause, be inclined to try intravenous injection of sterilised sulphate of soda solution. In one case of carbolic poisoning (suicidal) which I have seen this had a remarkable restorative effect.

I have to thank Mr. Douglas-Crawford for his courtesy in permitting me to publish the case.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Pathology of Dropsy.—Exhibition of Specimen.

A MEETING of this society was held on April 2nd, Mr. W. WATSON CHEYNE, the President, being in the chair.

The PRESIDENT, in bringing forward certain Alterations in the Rules recommended by the Council, said that after considerable discussion the council had decided to recommend the appointment of four sectional secretaries for the four departments of pathology—viz., (1) pathological anatomy and histology; (2) bacteriology; (3) experimental pathology; and (4) chemical pathology respectively. One senior or general secretary would organise the whole work of the society. There would also be four vice-presidents who would preside over four committees of the council corresponding to these four departments. The necessary alterations to the by-laws of the society to effect these changes were adopted by the meeting.

Professor E. H. STARLING made a communication on the Pathology of Dropsy. He remarked at the onset that he had only been able to perform experiments on healthy normal animals. He had not been able to apply to his hypotheses the only true test—viz., to experiment under diseased conditions. However, dropsy was an abnormal accumulation of normal fluid in the tissues due to a disturbance of the ballance between the production and absorption of fluid in the subcutaneous tissues and serous cavities of the body. He would limit his remarks to the "mechanical" form of dropsy due to simple obstruction, as met with in cases of uncompensated heart disease. The possible factors in the causation of dropsy were very numerous; thus there were some which could act by causing increased transudation and others which could act by causing diminished absorption—factor of diminished absorption negligible compared with product; but in his belief the factor of diminished absorption was negligible as compared with that of increased transudation. The factors involved in lymph production were both chemical and physical. As regards the former, the capillary walls presented no opposition to diffusion and thus there was always a change going on between the fluid within and the fluid without the walls. Wherever there was breaking down of big molecules into smaller and more diffusive molecules then there was increased diffusion. This would explain local inflammatory œdema, but would not explain the enduring or permanent dropsies as met with by the physician. The physical factors influenced filtration through the capillary walls and this depended upon (1) the intra-capillary pressure; and (2) the permeability of the vessel walls. The latter differed in different parts of the body; thus in the viscera the permeability of the vessel walls was much greater than it was in the limbs. They must differentiate between these two kinds of vessels. Now the fluid in the kind of dropsy under consideration collected in the latter where permeability was most difficult. It had been stated that "mechanical" dropsy was very readily explained by a rise of pressure in the veins and capillaries. But simple obstruction to a vein in an animal did not produce œdema. Rise of pressure alone would not produce œdema, it was necessary to alter the nutrition of the capillary wall—e.g., by lowering the vitality of the latter by tissue fibrinogen and other poisons or by producing hydræmia. If the vitality of the capillary walls was damaged by the injection of tissue fibrinogen or other poison, or by producing hydræmia, œdema resulted. Everything seemed to depend on the state of the capillary walls. It was certainly so as regards mechanical œdema by pressure of a tumour. Cardiac dropsy was a little different. In the first place it was difficult to see how there could be an increase of pressure in the capillaries in cardiac dropsy. He (Professor Starling) had made various experiments, employing Cohnheim's device of injecting oil into the pericardium, which demonstrated that there was actually a fall of blood-pressure in the capillaries in simple cardiac failure. It followed, therefore, that the prime change here was not mechanical but in the capillary walls. Just as in ischæmia, the walls became damaged by deficient nutrition and they were not then able to withstand even the normal blood-pressure. The problems presented by effusions into the serous cavities presented much the same solution as in dropsy of the limbs. He had designed various experiments in order to produce pleural effusion by a rise of capillary pressure but without success. But it was very easy to produce dropsy by the slightest damage to the capillary walls or to the pleural membrane All these experiments showed that if the vessel walls remained normal no fluid was effused. In the case of the peritoneum, however, it was possible that a rise of pressure took a rather more active part.

[1] THE LANCET, June 1st, 1895, p. 1362

[2] THE LANCET, August 28th, 1897, p. 537.

Dr. W. S. LAZARUS-BARLOW said he was very glad that Professor Starling had modified his views and had thrown over the idea that mere mechanical pressure could produce dropsy. He (Dr. Lazarus-Barlow) had raised the blood-pressure in the hind limb of a dog from 5 to 60 or 70 mm. of mercury and kept it at that for several hours, but had produced only a negligible quantity of dropsy. Moreover, if the filtration view was correct it ought to be possible to show that the first commencement of the dropsy occurred at the very moment at which the vascular pressure was raised. He had investigated this matter experimentally and had no hesitation in saying that it was possible to increase the venous, and therefore the capillary, pressure very considerably without the slightest evidence that fluid left the blood-vessels or passed into the tissues. For this purpose he made careful examinations of the specific gravity of the blood (arterial and venous), the blood plasma (arterial and venous), the specific gravity of the tissues, muscle, and skin, the specific gravity of the lymph, and the rate of its flow. In spite of a rise in the blood pressure in the veins of a dog to 50 mm. Hg., the normal being less than 4 mm. Hg., at the end of an hour no alterations in these values for the specific gravities were observed. On the other hand, it was easily possible to produce a dropsical condition of the dog's hind paw by completely arresting the flow of blood through the limb for an hour and then allowing the blood again to flow through the limb. Under such conditions the œdema made its appearance and was accompanied by the changes in specific gravity, &c., which were to be expected. That is to say, the specific gravity of the blood and blood plasma rose, while the specific gravity of the muscle and skin fell. He had found that the production of dropsy in this way was brought about with more certainty if the blood contained in the limb were simply arrested than if the limb were rendered completely anæmic and kept in that condition for an hour. This he explained by the supposition that starvation of the limb was a less potent factor than starvation combined with poisoning by the waste products of tissue metabolism. He believed that the real causes of dropsy were to be found in these two factors, starvation of the tissues and their poisoning by waste products. The actual manner in which the fluid left the blood-vessels was, he believed, an excess of the normal process by means of which the nutrition of the tissues was maintained. Normally when a tissue was functionating or when it was exposed to warmth its blood-vessels dilated and there occurred an increased amount of lymph flow. He thought that the same factors were at play in the pathological processes constituting the different varieties of dropsy. Upon this view the tissues would determine the occurrence of dropsy primarily and not the blood-vessels. No doubt the process became highly complicated in most cases, but he had never been able to understand how the supporters of the mechanical view of dropsy could explain the dropsy that occurred about the ankle when a surgeon ligatured the femoral artery in Hunter's canal, on the one hand, and the remarkable absence of dropsy in cases of congenital heart disease, in which the evidences of increased venous pressure were excessive, on the other. He maintained that the view which he put forward was a better working hypothesis than the other, that it was competent to explain a larger number of varieties of dropsy, and that it indicated lines of treatment which were more likely to be useful.

Dr W. EWART wished to refer to the clinical aspect of the subject. There was, he believed, a nervous factor in the causation of dropsical effusions and particularly in localised œdema—e g., that associated with abscess or acute gout. Here a vaso motor change was rendered evident in the redness. In the localised œdema of paralysed limbs there was also probably nervous influence Passing to the more general œdemas, and particularly to renal dropsy, his method of treating chronic tubal nephritis by feeding and drainage had lead him to believe that the central nervous control, stimulated by the toxicity of the blood, took the place of the local nervous influence in the localised œdemas. As soon as the dropsical fluid was allowed to escape—e g., by acupuncture—diuresis at once took place. He thought that this could be best explained by the hypothesis he had put forward.

Professor C. S SHERRINGTON remarked that it might be impossible to separate the action of the vessel wall from that of all the other tissues around it, but the vessel wall was the one constant element and justified the inference that this was the chief seat of change. He would like to ask what was the experimental evidence of changes in the vessel wall as regarded its permeability—using that term in its physical sense. There must be a very slight alteration in the nutrition in the vessel wall in cardiac disease.

Dr NEWTON PITT wished to refer to a question which had never been satisfactorily answered—Why was it that in mitral stenosis there was such a marked tendency to ascites and no œdema, while in mitral incompetence there was œdema rather than ascites? The late Dr. L. C. Wooldridge came to the conclusion that the blood change was the main factor in the production of dropsy.

Dr. W. P. HERRINGHAM, while admitting that the mechanical was not a satisfactory explanation, whatever the immediate cause of the dropsy might be—whether a drainage in the vessel-wall or in the tissues outside—and while admitting that malnutrition played an important part, could not help thinking that there were many facts which pointed to the immense importance of mechanical forces. For instance, even in generalised renal dropsy, if a patient lay on his right side, the right side of the face would be more swollen than the left

Dr. HALE WHITE remarked on the suddenness or rapidity with which the ascitic fluid might be poured out in hepatic disorder, a fact which he regarded as against the view that it was due to the contraction of the fibrous tissue within the liver. In some cases of the most extreme contraction of the liver there was no ascites. The largest amount of ascitic fluid occurred in cases where the peritoneum was damaged, as in chronic peritonitis, not in cases where the portal vein was obstructed.

Dr. ROSE BRADFORD, while agreeing that the amount of dropsy was not correlated to the degree of pressure, could not agree with Dr. Hale White in his explanation. He (Dr. Bradford) had always regarded the œdema of the legs in ascitic cases as due to a slight constriction of the inferior vena cava where it passed through the liver.

Professor STARLING, in replying, said that as regards ascites he had ligatured the main trunk of the portal vein, producing very great congestion of the intestines, but no ascites was produced at any time. This showed that the rise of pressure was not the essential change He had repeated Dr. Wooldridge's experiments but he had come to opposite conclusions to him.

Dr. F. S. TOOGOOD exhibited a specimen of a *Hydatid Cyst of the Heart* which had occurred in a man, aged 41 years, who presented no symptom besides progressive asthenia from which he ultimately died.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on March 21st, Mr. J. JACKSON CLARKE, Vice President, being in the chair.

Dr. E. CAUTLEY showed a man, aged 41 years, with extensive Generalised Degeneration of the Arterial System. The man had been a sailor for 20 years and for the last six years he had been a cab-driver. He had syphilis 15 years ago and had suffered from psoriasis for 10 years on and off. He came under observation last November for vomiting and abdominal pain. There was very marked thickening of the arteries, more especially of the abdominal aorta, which felt like a rigid, thick-walled tube. The arterial tension was not raised; there were no evidence of hypertrophy of the heart and no ocular changes. For a month he had a variable amount of albuminuria, but no albumin had been detected during the last three months. After the gastric symptoms had subsided he improved steadily on large doses of iodide of potassium. Dr. Cautley thought that the gastric symptoms were due to deficient nutrition of the stomach through the arteries supplying it being involved in the disease, and he raised the question whether the arterial degeneration was due to some form of syphilitic arteritis, although it was most unusual to find such a condition so late in the disease.—Mr. CAMPBELL WILLIAMS said that there were certain cardinal points in the case that were against the condition being syphilitic. The size, number, and amount of the involved arteries, together with the extreme slowness of the process, which had been going on for years without producing obliteration of any arterial lumen, were rather in favour of a diffused and early stage of atheromatous degeneration. The skin lesion was a coincidence. It was not a squamous syphilide but simply ordinary psoriasis occurring in a patient who happened to possess a former syphilitic history. Iodide of potassium was a drug that was of service in treating psoriasis as well as in treating syphilis.—Dr. CAUTLEY, in reply, agreed in the main with what Mr. Campbell Williams had said, but he thought it probable that the syphilis was largely responsible for the arterial disease, even if there was not a true syphilitic arteritis.

Mr. P. L. DANIEL showed a case of Enlarged Spleen with no Leucocytosis. The patient, aged 11 years, born in Yorkshire, had lived chiefly at Kingston-on-Thames, and had never lived abroad or in the fen country. There was a history of whooping-cough and indefinite illnesses at various times, but not of measles. The patient was admitted into Brompton Hospital under the care of Dr. T. H. Green as a case of early phthisis, there being pain in the left side and cough, while there was a swelling found in the left hypochondrium. There was no phthisis. In February, 1900, the patient was transferred to Charing-cross Hospital. The temperature was 99° F. The abdomen was slightly full but there was no obvious swelling. On palpation a tumour of firm, uniform consistence was felt extending from the left costal margin to within an inch of the outer part of Poupart's ligament and from the mid-line internally round the left loin to the erector spinæ behind. The edge was sharply defined and fairly thin. On the anterior edge were two or three notches. The tumour occupied the whole of the left loin except a finger's breadth above the iliac crest in the ilio-costal space. It was dull except at the lower angle which became resonant on inflation of the rectum. No band like that of colic resonance obtained at any time. It moved slightly with respiration. It could be taken between the hands in front and behind, but could not be moved to any extent. Above it extended to the fifth rib in the nipple line, to the seventh in the mid-axillary line, and to the eighth in the scapular line. It was slightly tender. The red corpuscles in the blood numbered 3,740,000 per cubic millimetre, the white corpuscles 12,000 per cubic millimetre, and the amount of hæmoglobin was 70 per cent. There were no symptoms beyond occasional pain in the side and breathlessness which had developed during a stay of some months in the hospital. Twelve months later (in 1901) there were pain in the side, languor, and breathlessness; a doubtful trace of blood in the sputum at times; otherwise the patient had been quite well. At the present time the tumour remains as before. The blood showed 3,700,000 red corpuscles per cubic millimetre and 9000 white corpuscles, the amount of hæmoglobin being 60 per cent. There was little or no enlargement of the lymph glands. The patient was said to have bled a few drops from the nose once recently.—Dr. CARTER regarded the case as one of pseudo-leukæmic enlargement of the spleen. He thought that it resembled cases of much enlarged spleen and anæmia seen in infants, and he suggested that the condition had been present since infancy. The child was not now markedly anæmic and in all probability the disease was a hyperplasia of the spleen which was no longer progressive.—Dr. C. S. JAFFÉ made a few remarks and Mr. DANIEL, in reply, said that he thought that the case was one of splenic anæmia.

Mr. DANIEL also showed a case of Bilateral Ossification of the Tendo Achillis and Plantar Ligaments with Skiagram. The patient, a man, aged 35 years, had suffered from rheumatic (?) pains all his life. His father was also rheumatic. The patient had gonorrhœa when he was 22 years of age and a sore on the penis which disappeared in 14 days by local applications only. No evidence of syphilis was obtained. From earliest recollection he had had tender feet, but when he was 18 years of age he was considerably exposed to bad weather, and he took a chill and suffered great pain in both feet, especially in the heels. Since then he had always been more or less crippled. The attack of gonorrhœa four years later did not appear to have affected the condition in any way. He often had marked shooting pains in the pectorals, the muscles of the back, the deltoids, and the glutei, rendering him unable to move his limbs, the joints appearing fixed. There was no swelling of the joints noticed. He was able to work a tricycle with fair comfort, but he walked with difficulty, and could hardly walk at all when barefooted. Sometimes his boots hurt him very much, but on the whole he was more comfortable in them than when his feet were bare. He was strong, well built, walked very lame, and had a marked stoop. There was no evidence of myositis ossificans and he had good movement in the back and all the joints, including the ankles, which he could flex and extend perfectly when his feet were off the ground. The heels, which were slightly enlarged, were glossey but not red, there was some rigidity of the great toes, and the arch of the foot was slightly depressed. The point of maximum tenderness was at the tip of the heels, but the whole region was tender. An irregular mass could be felt and seen on either side of, and probably on, the tendo Achillis for one and a half inches above the os calcis. Ossification in the plantar ligaments could not be felt. Cold, damp, and walking increased the pain. The condition had been progressively worse. Liniments, especially of iodine, and iodine internally gave slight relief. The condition had been treated for years as osteo-arthritis, of which there was no evidence. No other tendons were involved.—Mr. JACKSON CLARKE said that he regarded the formation of bone in the tendo Achillis and the long plantar ligament as essentially of the same nature as the ossification of the periosteum and ligaments observed in the vertebral column in osteo-arthritis of the spine. The patient said that his father had suffered from gout and a similar predisposition probably underlay the patient's troubles. He (Mr. Clarke) thought that a thorough course of medical treatment and a course of spa treatment at Buxton or Bath followed, if necessary, by drilling the bone at the base of the osteophytes, offered the best chance of success.—Mr. WILLIAMS made a few remarks.

Mr. DANIEL also showed a case of Enlarged Liver with Jaundice of Uncertain Cause. The patient, a labourer, aged 54 years, had always been healthy and had never lived abroad. He was not over-addicted to alcohol, two pints of beer daily being the average quantity taken by him. The present illness began on July 18th, 1900, with listlessness and a feeling of being out of sorts and loss of appetite. There was no pain of any kind. The urine was high-coloured and occasionally the stools were light-coloured. He was told that he was getting yellow and the colour increased in depth till August. He was at home from August to November with varying depths of jaundice and the signs as before. There was also swelling of the feet and the abdomen at night, which disappeared by the morning. There was no history of pain or colic at any period. He was treated for dyspepsia and by mild purgation. He resumed work in November. He was still jaundiced but was better in health. The jaundice continued and varied in depth with constipation till February of this year when the old symptoms returned. There was some wasting. At the present time there was intermittent fever, the temperature ranging from 101° to 98° F. The patient was thin and moderately jaundiced. The liver extended from the fifth rib on both sides to the level of the right anterior superior spine, completely obscuring the stomach resonance. It was uniformly smooth, firm, and the edge was sharp. *Just to the right of the* umbilicus was a localised swelling of the size of a small orange, partly separated from the main mass by a slight sulcus. This was free from tenderness, *slightly moveable*, and non-fluctuant (*? gall-bladder*). The spleen was normal. There were no petechiæ and no ascites was present. The urine and stools varied slightly, the latter being now of a drab colour. The insidious onset of the illness, the absence of colic, the slight emaciation, the partial obstruction to the common bile duct, the possibly enlarged gall-bladder with the size of the liver, the normal spleen, and the pyrexia, made the case a complex one.—Dr. CAUTLEY [illegible] either malignant disease of [illegible] osis. He did not find any [illegible] of the gall-bladder and thought that prominence of the rectus muscle on that side might simulate such a condition.—Mr. E. W. ROUGHTON also commented on the case from a surgical point of view.

Mr. DANIEL also showed a fourth case—one of Supra-hepatic Abscess treated by the Trans-thoracic Route. The patient, a man, aged 29 years, had been a signalman in the navy. He had had remittent fever and dysentery (mucoid stools with tenesmus but no blood) in 1896 when on the China station. Since then he had had three attacks of what was called "gastritis," and the condition had been treated as such. On one occasion he was thought to have a *swelling in the right side which was diagnosed as* abscess of the liver, but it disappeared apparently in the course of six weeks. He left the navy in 1898 and these attacks had all [illegible] and 1900. [illegible] and last [illegible] se of the [illegible] e patient was flatulent, anæmic, and constipated. The liver was not *palpable or enlarged and the spleen* was in a *similar condition.* He had had no definite physical signs, but abscess of the liver was suspected. On March 16th, having been treated for dyspepsia, further notes state that there was exacerbation of pain in the epigastric region. *One* month later (April) deficiency of movement of the right chest was noted and a small effusion of pus was suspected. The liver was still not palpable. The patient was admitted under Dr. Cautley's care three weeks later with an enlarged liver reaching to the umbilicus; he looked very ill, thin, and anxious. His skin was of an earthy, sallow colour. The temperature was 100·4° F. He was intensely depressed in spirits. *A large swelling existed in the right side, filling up* the whole epigastric and upper part of the right lumbar region. It was firm and of elastic consistence, but there was no definite edge. There was no fluctuation and the swelling was dull on percussion. This impaired resonance extended upwards to the fourth rib on both sides in front and to within an inch of the angle of the right scapula behind. The breath sounds were deficient over the right base. The apex-beat of the heart was displaced upwards and outwards considerably. There was tenderness in the epigastrium which was most marked when *the patient was lying* on his back. *The patient slept* well, but *perspired a great* deal at times. There were aching pains in the tip of the right shoulder; slight leucocytosis was present. The aspirating needle in the eighth space of the scapular line *revealed a reddish-brown, chocolate-like* fluid. This consisted of débris and disintegrating cells and gave a pure culture of the bacillus coli communis. The following operation was performed. One and a half inches of the right rib were removed in the mid-axilla, *and the diaphragm* was *pushed up into and above the* wound. The diaphragmatic pleura was raised and sewn to the periosteum and parietal pleura. The diaphragm was incised and three and a half pints of pus escaped; this was odourless. The extent of the cavity could not be ascertained by the finger but the sac was lined by soft thick granulations. A one-inch tube was inserted. The temperature fell to normal, having been remittent. The patient picked up rapidly and gained weight, the appetite returned, and he was up in one month. Scrapings of the sac wall showed amœbæ. The heart returned to its normal position. At the present time (11 months after the operation) the patient says that he never felt better in his life. The lung had expanded. In this case the notable points were the length of time after leaving the East before the patient developed definite signs of liver abscess; the intensity of the gastic irritability; the shoulder tip pain; and, as Dr. Cautley indicated, the surprisingly rapid development of the abscess. Mr. Daniel considered the cavity to be limited by the coronary ligaments and liver and diaphragm—therefore, the abscess was supra-hepatic.—Dr. CAUTLEY said that when he first saw the patient he examined him carefully for evidence of hepatic abscess but could find no such evidence. The increase in size of the abscess was extraordinarily rapid.—Mr. JACKSON CLARKE made a few comments.

Mr. ROUGHTON showed a Man whose Femoral Artery had been tied for Popliteal Aneurysm.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 19th, Mr. F. Farrow, the President, being in the chair.—Dr. F. W. Eurich gave a *Microscopical Demonstration.*—Mr. Percy Lodge *showed an Inhaler for use with Chloride of Ethyl.*—Dr. C. F. M. Althorp showed a patient with a Tumour of the Palate.—Dr. Campbell showed a Cretin Dwarf.—Dr. Jason Wood showed: (1) A patient with very extensive Cancer of the Neck; and (2) the Temporal Bone and Cerebellum from a case of Cerebellar Abscess.—Dr. James Kerr showed a case of Sarcoma of the Conjunctiva.—Dr. Kerr read a paper based on 50 cases of Tobacco Amblyopia seen in the past year. It was, he said, important to exclude kidney disease by testing the urine and *tabes by testing the knee-jerks; then in a case of failing* vision in middle age not improved by glasses there remained cataract, glaucoma, and toxic amblyopia as common causes. Cataract should only be diagnosed after inspection in the dark room. The colour scotomata differentiated from simple glaucoma. The ordinary test with a square centimetre of coloured paper failed to detect about one-third of the scotomata; smaller objects, such as a pin-head with red sealing-wax on it, were useful; it might also be necessary to test in a reduced light. One-fifth of the number showed marked unilateral *affection so that each* eye should be tested separately. Hypermetropia was present in *three-quarters of the hospital cases. Other debilitating* circumstances were frequent, and although it generally required at least three ounces of tobacco weekly for many years, with reduced health, as in the case of a woman quoted, one and a *half* ounces had produced a *toxic result in less* than a year. The only treatment required was to stop tobacco; strychnine hastened recovery. The importance of always excluding tobacco effects—often masked by glaucoma, *cataract, or cerebral lesions—was insisted on, their detection* changing a hopeless prognosis as to vision into a very favourable one.—Dr. W. Arnold Evans (medical officer of health of Bradford) read a communication on an Outbreak of Small-pox in Bradford. He said that on Dec. 26th, 1900, he was asked by a medical practitioner to see two cases of suspected small-pox in consultation and was at the same time informed that the medical practitioner had about *three weeks previously* attended in the same house a case which he considered to be one of varicella in an adult. During the few days following *some* other cases of small-pox were reported in the same *locality*, all the infected persons being either friends or relatives of the patients who first came under his notice. About 16 days after the occurrence of the early cases an intimation from the medical officer of health of a neighbouring town showed *that there was* in all probability an outbreak in another part of the city. An investigation proved this surmise to be correct, for a girl was found *in the crusting stage of variola*, having been attended by a medical man for varicella. It also transpired that this girl was a relative of, and had been *infected* by, one of the patients seen on Dec. 26th, 1900, so that what at first sight appeared to be two outbreaks of small-pox was really one. The outbreak up to the present time had consisted of 27 cases, seven of which were those of unvaccinated persons whose *ages* varied *from* six years to 36 years, the other 20 cases being those of persons who showed some evidence of having been vaccinated in *infancy. Although some of the cases of the* unvaccinated class were severe no deaths had occurred in either group. Dr. Evans thought that there should be very little difficulty in distinguishing cases of variola or varioloid from varicella, provided the *following points* were given a due amount of attention—viz: (1) the distribution of the eruption which in small-pox was most copious on the face, wrists, *hands, ankles*, and feet, and which in varicella occurred chiefly on the trunk; (2) the constitutional symptoms which in a case of small-pox with a copious eruption were severe and in varicella mild; and (3) evidence of vaccination, small-pox being very rare in well-vaccinated persons under 10 years of age. Dr. Evans said that he had several times seen severe cases of small-pox mistaken for erysipelas, the misleading symptom being swelling of the face and eyelids. He stated that a characteristic of the present outbreak was the comparative mildness of the attack both in vaccinated and unvaccinated persons. Referring to individual cases Dr. Evans instanced two of small-pox in pregnant women; one woman was delivered in the eighth month, within seven days of the onset of the attack of small-pox. The child was vaccinated immediately after birth, and although subsequently fed at the mother's breast escaped an attack of small-pox. The other woman miscarried at about the fifth month; the fœtus, which had evidently been dead for a considerable time previously to birth, showed signs of a copious eruption of small-pox, chiefly on the back.—The paper was discussed by several members and Dr. Evans replied.

British Gynæcological Society.—A meeting of this society was held on March 14th, Dr. J. A. Mansell Moullin, the President, being in the chair.—Mr. Furneaux Jordan (Birmingham) showed a Fibroid Uterus removed from a woman, aged 49 years, who had had two children. She made a good recovery.—Dr. Macnaughton Jones read notes of a case of large Angioma of the Liver removed from a woman, aged 27 years, who had had three children, the youngest being 17 months old. The tumour occupied the right hypochondrium and part of the lumbar region, simulating closely on examination a large moveable kidney. The abdominal swelling was first noticed more than a year previously. The patient's symptoms were great pain radiating across the abdomen and down to the inguinal region, occasional vomiting, and of late rapid loss in weight. The tumour was situated in the free margin of the liver, immediately to the right of the gall-bladder, projecting more on the deep than on the convex surface of the liver. Some deep fissures marked its upper surface, and over its upper and lower aspects there were yellow and dark brown mottled patches. The base of the tumour was gradually ligatured off by passing Deschamp's needles armed with strong silk through it, and ligaturing it in sections. It was thus isolated and finally clamped before it was divided, strong catgut sutures being also used to secure it. It was thus removed with comparatively little loss of blood. She never, however, recovered from the shock, and sank 18 hours after the operation. The tumour, when shrunken after removal, measured three and a quarter inches by three inches. Histologically, it was an angioma of the liver and there was no evidence of malignancy.—Dr. Macnaughton-Jones also read the notes of a case of Primary Miliary Tuberculosis of the Breast, a condition which appeared to be very rare. In support of this view he quoted Mr. Marmaduke Sheild, Mr. Watson Cheyne, and Mr. Shattock, but Mr J. H. Targett, from the examination of several hundred mammary tumours, considered that tuberculosis of the breast was much more common than was supposed.—Mr. W. Roger Williams read a paper on the Pathology and Surgical Treatment of Uterine Tumours in the Nineteenth Century. After outlining the progress of pathological views from Heister and Hunter to Virchow, he said that Waldeyer pointed out that the doctrine of continuous cellular development ignored the specificity of the tissue elements as revealed by embryology; and though Virchow clearly distinguished carcinoma from sarcoma, it was owing to Waldeyer's teaching that they now looked to pre-existing epithelial cells for the germs whence cancer arose. In 1875 Cohnheim put forward the view that tumours arose from sequestered fragments of the germinating tissues detached during embryonic life. Such fragments had been since found in every part of the body that had been specially examined for them. The uterus was no exception. The track of the Wolffian and Müllerian ducts was strewn with débris of this kind. Mr. Williams then dealt *seriatim* with several varieties of uterine tumours, explaining their origin on this hypothesis. Cancer, he said, had been ascribed to many organisms. Bacteria had been found in uterine myomata, but nothing justified the assumption that the latter were due to the former. Malignant and non-malignant tumours were derived from elements having different developmental tendencies, and the conversion of non-malignant into malignant types need not be anticipated. For the removal of myomata he preferred the vaginal route in suitable cases. He considered that the removal of myomata by abdominal section should be regarded as a means for dealing with certain exceptional cases rather than as the routine treatment.

North of England Obstetrical and Gynæcological Society.—A meeting of this society was held at Sheffield on March 15th, Dr. T. B. Grimsdale, the President, being in the chair.—Dr. Arthur Wallace (Liverpool) showed a specimen of Carcinoma of the Corpus Uteri removed by vaginal hysterectomy. The patient made a good recovery.—Mr. Walter Thompson (Leeds) showed a Uterus with Fibromyomata undergoing degeneration. The soft, brain-like appearance of the growth, together with the clinical features of the case, strongly suggested malignancy; the microscopic examination, however, gave no evidence of the latter. The growth was removed by hystero-myomectomy. Death occurred from intestinal obstruction produced by adhesion of a coil of bowel to the line of suture of the peritoneum.—Mr. R. Favell (Sheffield) showed: (1) A Vesicular Mole which, dating from the last normal period, had enlarged the uterus so that its fundus reached two inches above the umbilicus at the third month, at which time the mass was expelled; (2) a Carneous Mole of the size of an orange which had been retained in the uterus until the end of the seventh month; and (3) a Fœtal Monster with a Large Sacral Meningocele, together with Absence of the Abdominal Wall.—Dr. Martin (Sheffield) showed the Ovaries removed from a case of Intractable Hæmorrhage which had resisted all other treatment, including curetting. Both ovaries were much enlarged and cystic; the right one was prolapsed and moveable and the left one was adherent in its normal position, so that it was not felt on ordinary vaginal examination.—Dr. Sinclair (Manchester) related a case of Cæsarean Section. The operation was successful for both mother and child.—Dr. J. B. Hellier (Leeds) showed drawings and photographs of a case of Congenital Deformity of the Skull. The deformity consisted of a groove surrounding the head at the level of the orbits anteriorly and the posterior fontanelle behind, so causing an unusual prominence of the frontal and occipital regions. The condition was thought to have been caused by the constriction of an amniotic band.—The President read notes of a fatal case of Phlegmasia Alba Dolens. The patient came under his care at the Liverpool Royal Infirmary three weeks after confinement. The labour was normal, but there was some rise of temperature during the early part of the puerperium, for which the uterus had been washed out. The right thigh and leg began to swell on the tenth day. When admitted to the infirmary there were frequent rigors and irregular high temperature and enormous enlargement of the right thigh and leg. The left thigh and leg were normal to all appearance. There was no vaginal discharge; the uterus was moveable, it was not much enlarged and was not tender. The streptococcus was found in the blood. Anti-streptococcic serum was used once or twice daily and produced temporary improvement, but the patient eventually died one month after admission—namely, seven weeks after her confinement. At the necropsy infarcts were found in the spleen and the right lung. The blood gave practically pure cultures of streptococcus but no staphylococci. The uterine veins were thrombosed and there was pus in the perivascular connective tissue. The left femoral vein and external iliac were full of pus extending up to the vena cava. The right femoral vein was thrombosed. It was interesting to note that during life there were no local signs of the suppurative phlebitis in the left leg, the pain and swelling being on the right side.

Newcastle-upon-Tyne Clinical Society.—The fifth meeting of the session of this society was held on March 7th, Dr. F. Hawthorn, the President, being in the chair.—A letter from the British Congress for the Prevention of Consumption to the society inviting delegates to the meeting in London on July 22nd was read.—Dr. W. T. Hall showed a patient in whom the Heart was found to be on the Right Side. A discussion followed as to diagnosis between transposition of viscera and fibroid phthisis drawing the heart to the right side, the majority deciding in favour of the latter condition.—Dr. F. O. Coley showed three cases of Nervous Disease. The first was that of a girl, aged seven years, with mitral regurgitation, partial hemiplegia, with previous albuminuria. In the second case a girl had pain and weakness in both legs and tenderness on pressure on both calves Walking was rendered unsteady, the child taking hold of anything that might be near for support There was no history obtainable of scarlet fever, diphtheria, or arsenic administration There was absence of both knee jerks In the third case, that of a boy, seven years old, there were incoördination of movements on walking, slight right facial paralysis, and exaggeration of the left knee-jerk. Previously walking had been impossible for a time — Dr W E Harker showed some Plague Bacilli obtained from the spleen of a rat killed on a plague infected vessel in which 13 cases of plague among the crew had taken place with 4 fatalities The macroscopical examination of the body of the rat showed œdema of the hind leg and the liver enlarged to three times, and the spleen to four times, the natural size —Dr G G Turner showed the specimen from a fatal case of Intussusception in a child on whom he had operated The child was collapsed before operation A lateral anastomosis was effected, as the condition was irreducible (even after death) Its position was just above the ilio cæcal valve

IPSWICH CLINICAL SOCIETY —A meeting of this society was held on March 14th, Mr James Hossack being in the chair.—Dr Stanley Hoyland showed a child with a Patent Foramen Ovale She was subject to cyanotic attacks from birth —Dr R W Brogdin showed (1) a young lad, 15 years of age, with a large, rapidly growing Bronchocele, and (2) a man with an Enlargement of the Lower End of the *Left* Femur and also of the *Left* Tibia The patient had been under observation for a year. His general condition was extremely good He was inclined to think that the swelling was sarcomatous —Dr Francis Ward showed (1) a Card Specimen and also Microscopic Slides from a case of Symmetrical Gangrene of the Toes in a young infant; and (2) a Specimen of Blood in a very advanced case of Hodgkin's Disease —Dr W A Gibb showed a rapidly growing Tumour of the size of a pigeon's egg which he had removed from the ear of a young lad He commented on the comparative rarity of these cases and the fact that it had followed an injury. It was probably fibro-sarcomatous in character —Mr Hossack showed a seven months' Anencephalic Fœtus —There was a discussion afterwards

Reviews and Notices of Books.

The Early Days of the Royall Colledge of Phisitians, Edinburgh By R PEEL RITCHIE, M,D Edin Edinburgh George P Johnston 1899 Pp 330

DR ROBERT PEEL RITCHIE, in his capacity of President of the Harveian Society of Edinburgh, delivered at the 114th festival of that society, in June, 1896, the address which has been expanded into the book now before us This fact explains why Dr Ritchie commences his book with a section entitled "William Harvey," which at first appears strange, seeing that Harvey died in 1657 and the Royal College of Physicians of Edinburgh was not founded until 1681 But, as Dr Ritchie shows, Harvey's "example and influence played no small part in the future founding of the Edinburgh College In Harvey's time there was no university or medical school in England, Scotland, or Ireland sufficiently well equipped to give a medical education worthy the name, and from 1617 various attempts had been made in Scotland to found a college of physicians Dr Ritchie thus sets forth the connexion of Harvey with the aforesaid attempts The first attempt was made in 1617, when James I (of England) revisited Scotland Two years previously Harvey had been chosen to teach and to lecture in London The second attempt was made in 1630 and two years previously Harvey's great work on the circulation had appeared The third attempt was made in 1657, shortly after Harvey's term of teaching had ended, and he had handed over the Lumleian lectureship to his intimate friend, Sir Charles Scarborough, whose help and influence contributed so greatly to the success of the fourth and final attempt The project of a College of Physicians was bitterly opposed by the universities, the town council, the chirurgeons, and the clergy, who though at this date mainly Presbyterian were no less opposed to the formation of the College than had been the Episcopalians in former years The opposition to the scheme seems to have been very skilfully overcome, mainly by Dr. Robert Sibbald who was afterwards knighted

How the matter was engineered must be sought for in the pages of Dr Ritchie's book, but we may say here that the protagonists were Sibbald, the Earl of Perth, Lord Melfort, and Sir Charles Scarborough, the King's physician The charter was finally obtained on Nov. 29th, 1681, being, appropriately enough, St Andrew's day, The claim of the College was not a very far reaching *one* The *proposers* of it were willing not to go in for teaching or for dissections, as did the surgeons, so that their candidates for incorporation might be able to *practise "flewbothomes"* But what the physicians did claim was "to have authority to supervise Medical Practice in the City, Suburbs, and *Liberties thereof, and to practise Medicine therein* shall only be permitted to those Physicians licensed by the Fellows of the College after trial and examination, and no one shall be admitted Socius until he has first obtained the licence to practise from the College' The charter, however, gave the College no power to examine Scottish graduates, but Scottish graduates had to have the licence of the College to practise

Within a period of just under three years from the foundation of the College four great reforms were carried through—namely, the compilation of the Edinburgh Pharmacopœia, the opening of a dispensary for the sick poor, the institution of regular examinations for the licence to practise, and the medical conferences at the College which were a form of what would now be called meetings of a medical society They were held monthly and the first discourse was delivered by the President, Sir Archibald Stevenson, "on the Polypus Cordis, to the great satisfaction of the Colledge" The Pharmacopœia, however, owing to opposition on the part of some of the Fellows, did not appear until 1699, a delay of 18 years In view of the controversy which has lately taken place concerning the title of the King it is interesting to note that the book was dedicated "Serenissimo Gulielmo II D G Scotiae, Angliae, Franciae, et Hiberniae Regi " There had, of course, previously only been one William of Scotland who began to reign in 1165

The moving spirits of the College were Dr Archibald Pitcairn and the four knights—Sir Archibald Stevenson, Sir Andrew Balfour, Sir Thomas Burnett, and last, though not least, Sir Robert Sibbald Dr Ritchie gives full biographical notices of these five eminent men, and with regard to Sibbald expended a great deal of time and trouble—albeit a labour of love—in ascertaining the date of his death and the place of his burial He died on August 9th, 1722, and was buried in "Phesdoes ground," Sunday, August 12th, 1722 Phesdo was John Falconer of Phesdo and his ground was in Greyfriars Kirkyard Dr Ritchie gives a picture of it as it now is—as dismal as that at the gate of which "Poor Jo" used to sit

No stone marks Sibbald's memory and one might well, we think, be subscribed for Dr Ritchie's book is full of interesting facts and is a monument of painstaking literary research The type, illustrations, paper, and general printing of the work are, as is to be expected in an Edinburgh book, excellent

Rectorial Addresses delivered before the University of Edinburgh, 1859-1899 Edited, with an Introduction, by ARCHIBALD STODART WALKER, M B, F R C P Edin Pp xxxvi -337 London Grant Richards 1900

DR STODART WALKER has been excellently well inspired to produce this volume which contains a 'baker's dozen" of addresses delivered before the University of Edinburgh by the distinguished men who during 40 years past have filled the office of Lord Rector. A mere list of the names of the contributors—which includes, among men less eminently distinguished, Mr. Gladstone, Mr. Carlyle, Lord Rosebery, and the first Lord Iddesleigh—suffices to challenge attention for the work. And the addresses themselves amply reward the attention. In every case the preparation of the address demanded an effort on the part of the speaker and the efforts of such men are not fruitless. The results are strangely various and probably no one will peruse them without surprise. For example, it is not a little strange to find Mr. Goschen discoursing with great effect upon the part which imagination plays in the prosecution of serious studies, although the reader rises from the perusal of his speech with the clear perception that if there is one field in which more than in any other a cruel experience forces home upon her pupil the need of entering by imagination into the thoughts, motives, and point of view of an opponent that field is politics. Most readers will probably take up this volume with the expectation that Mr. Gladstone's scholarly tastes and ready sympathies will make him *facile princeps* in the capacity of Lord Rector. But in this we think that they will for the most part own themselves mistaken. In "the work of the university as a great organ of preparation for after life," and again in "the place of ancient Greece in the providential order of the world," Mr. Gladstone found very congenial themes, in fact, themes that were congenial overmuch. There is something "donnish" about his addresses both in form and substance which makes the reader feel that they might quite fittingly have been delivered in a classroom and from a professorial desk. They want the breezy, open-air character which should accompany, should even be the characteristic feature of, utterances coming from those whom the outer world has absorbed and by absorbing withdrawn them from a direct share in the pre-occupations of a professed and cloistered student life. The feeling arises that a Lord Rector who too readily falls into line with the march of college thought and expression fails in the highest function of his office, which is to electrify the scholastic body by bringing into contact with it the negative pole of a personality charged with the influence of the great world outside. For a very similar reason Thomas Carlyle falls short of pre-eminence in this company. He also is too unworldly for the post. If we were called upon to adjudicate upon the comparative merit of these deliverances we should have no difficulty in singling out Lord Robertson's address, delivered in 1895, as being quite an ideal performance. And this involves no disparagement of Mr. Goschen's most admirable lecture on the uses of imagination to which we have already alluded, or of Lord Rosebery's pithy and elegant reflections on the highest forms of patriotism. Nor, again, do we under-value the sympathetic sentences in which Lord Moncrieff linked the present university with its own past. All these were admirable, each in its own way and every one, indeed, indispensable to the completeness of the collection considered as an anthology. But Lord Robertson, as it seems to us, struck the exact note with unrivalled precision in his address upon the public value and public duties of disciplined intellect. The subject was one which could only be dealt with effectively by a man who stepped aside for the purpose from the regular course of a public career. It was, therefore, peculiarly fit for a rectorial address and Lord Robertson's matter and manner both were equally admirable. Nothing, indeed, could have been more appropriate to the place and time than the delicate irony of his style or the robust tone of his admonitions. Take, for example, the following passage as a specimen of these qualities: "Of the mental habit which I describe as that of culture it is a characteristic not to overrate education itself. The tendency to do so arises from an incomplete view of the panorama of life—a blindness to all but those mechanical powers which grind out uniform results. Individual education—the education of school or of school and college combined—is strong, but other things are stronger—race, character, religion, sentiment, interest in the past, loyalty to persons, knowledge of the world, business capacity, above all, the vast accumulated funds of wisdom and guidance which are covered by the invidious term prejudice and the august name of authority. The appreciation of these elements, and especially of their due weight in a civilised community, is a sure criterion of cultivated intelligence."

We must not, however, indulge in quotation. The book, suffice it to say, affords a collection of most unusual interest of essays by representative men to which its editor has prefixed a thoroughly appreciative and very serviceable introduction.

Diseases of the Nose and Throat. By F. DE HAVILLAND HALL, M.D., F.R.C.P. Lond., and HERBERT TILLEY, M.D., B.S. Lond., F.R.C.S. Eng. Second edition. London: H. K. Lewis. 1901. Pp. 605, two Coloured Plates, and 80 Illustrations. Price 10*s.* 6*d.*

THE first edition published by Dr. de Havilland Hall was fully 50 pages less than this issue which has undergone a careful revision and enlargement, and the hand of Dr. Tilley is plainly seen in some parts, especially in the chapter on the Frontal Sinus.

As a handbook the volume as it stands at present is highly to be commended; it possesses the great merit of laying down with decision and directness the line of treatment to be adopted under various conditions, and with the aid of the reasonably comprehensive list of formulæ at the end will enable students and practitioners to recognise and treat most conditions of the throat and nose that do not necessitate the skilled hand of the specialist.

The theory of Bosworth that non-specific perforation of the septum is due to the erosion by dust, &c., is said here to be confirmed by the fact that cement factory hands are frequently thus afflicted and that they constantly introduce the finger into the nose and thus abrade and eventually perforate the structure. We do not think that this proves Bosworth's theory, but it materially aids in substantiating the view that constantly picking the nose is the cause, the irritating dust being merely the excitant. Ulcerative processes of the tonsil, we think, might receive more attention in the next issue. The illustrations are frequently too sketchy and not all of them, notably that of adenoid vegetations, true to life. With these exceptions and especially as a text-book the work deserves a wide popularity.

Text-book of Histology: including the Microscopic Technic. By Dr. PHILIPP STÖHR, Professor of Anatomy at the University of Würzburg. Third American, from eighth German, edition. Translated by Dr. EMMA L. BILSTEIN, formerly director of the laboratories of Histology and Embryology, Woman's Medical College of Pennsylvania. Edited, with additions, by Dr. ALFRED SCHAPER, Professor of Anatomy, University of Breslau, formerly Assistant Professor of Histology, Harvard Medical School, Boston, Mass. 301 illustrations. London: Rebman, Limited. 1901. Pp. 432. Price 14*s.* net.

WE have to welcome this, the third American edition of Stöhr's Handbook, translated without alteration from the eighth German edition, though still possessing the editorial additions to text and illustrations which appeared in the previous American issue. That the book is extremely popular, and deservedly so, both in Germany and among English-speaking students is shown by this rapid multiplication of editions. Professor Minot in his introduction describes the work as "combining scientific thoroughness with simplicity, conciseness, and clearness of exposition," and anyone using the book must admit that this description is fully justified. The most characteristic and strongest parts of the work are, perhaps, the technical appendices to the various chapters with their extremely practical directions for the obtaining and preparing of histological material. Regarding histology as a branch of anatomy the author rigidly confines himself to what may be actually demonstrated, and it is this probably which leads him to eschew all reference to the theories which have been invented to explain the appearances presented by striped muscle, and even to avoid any nomenclature of the varieties of leucocytes, though this may lead to some bewilderment of the student when he reads other works. The description of the liver is extremely good, though we miss any reference to Kupffer's cells. The descriptions and illustrations of the organs of special sense are also excellent.

The chapters on Microscopic Technic are found at the beginning and end of the volume, and the methods are most judiciously selected to combine simplicity with efficiency. The illustrations to the book have always been distinguished for their excellence, and in the present edition they are well and carefully reproduced. We notice a printer's slip on page 99 and a transposition of letters in Fig. 253, but the volume is generally well printed on good paper and reflects credit on the publisher. It would be difficult to find any book in English on histology which more fully meets the requirements of the student or even of the professional histologist than the work under review.

Laryngeal Phthisis, or Consumption of the Throat. By RICHARD LAKE, F.R.C.S. Eng., Surgeon Laryngologist, North London Hospital for Consumption; Surgeon, Metropolitan Ear and Throat Hospital; Surgeon, Royal Ear Hospital; Surgeon for Diseases of the Throat and Ear, Trinity College of Music. With 36 Illustrations, 21 of which are coloured. London: Rebman, Limited. 1901. Pp. 94. Price 7*s.* 6*d.* net.

THE importance of tuberculosis of the larynx is frequently under-estimated, for it is looked upon as a complication of pulmonary phthisis of no great moment, and as it is often considered to be peculiarly irresponsive to treatment it has been greatly neglected. Yet it may truthfully be said that of all the common concomitants of tuberculosis of the lungs laryngeal phthisis is the most important and its treatment at the present day is by no means unsatisfactory. Mr. Lake has done well to put before the medical public this interesting account of the present position of our knowledge of this subject, and it is obviously firmly founded on fact, for it is based on the observation of more than 300 cases. Whether tuberculosis of the larynx is ever truly primary is perhaps doubtful, though from *a priori* considerations it might reasonably be imagined that infection from the inspiration of the tubercle bacilli might not infrequently occur. In the vast majority of cases, however, it is distinctly secondary to tuberculosis of the lungs, and it appears from Mr. Lake's statistics to be especially liable to occur in those engaged in sedentary occupations and to be much more common in men than in women. The chief symptoms directly traceable to the lesion are hoarseness and dysphagia, and this latter symptom is in itself sufficient warrant for energetic treatment, for the pain is so severe as in many cases to interfere seriously with the taking of nourishment. This pain is chiefly due to the pressure on the tender epiglottis.

The section on Treatment is necessarily the most important, and Mr. Lake lays stress on the value of treatment directed to the improvement of the general health. As to local applications the author speaks very favourably of formalin and protargol. If the ulcerations are especially well marked the curette should be used early, but after every scraping formalin or lactic acid should be rubbed in. When the epiglottis is very extensively diseased its complete excision by means of the galvano-cautery snare is advised. A convenient form of cutting forceps devised by Mr. Lake is figured and described. The prognosis is always grave, but it has improved markedly with modern treatment. 21 coloured figures are given illustrating the various lesions of the larynx and a table is appended supplying some details of the 320 cases observed by the author.

Altogether the work is clearly and concisely written and it will serve as a useful introduction to an important subject.

LIBRARY TABLE.

Notes on Physiology. By HENRY ASHBY, M.D., F.R.C.P. Lond., Physician to the Manchester Children's Hospital, Demonstrator of Physiology, Liverpool School of Medicine. Seventh edition. London: Longmans, Green, and Co. 1900. Pp. 406.—Napoleon was accustomed to say that the history of France should either be compressed into one volume of moderate size or should be expanded into 20. The same may be said of physiology. The subject is so large that if only the leading points be mentioned a small volume is sufficient, but if details are to be discussed, differences of opinion pointed out, and the arguments for and against particular views fairly weighed, an encyclopædia is required. Dr. Ashby's little volume, which is well known to students, belongs to the former class of treatises, and as a rule is very well and intelligently written. Occasionally, however, space is occupied which might be better utilised. For example, in discussing the velocity of the flow of blood in the arteries Dr. Ashby remarks: "Various instruments are employed for this purpose, the *stromuhr* of Ludwig and the hæmatachometer of Vierordt being the principal." But the names of these instruments are unaccompanied by any description or illustration, and they must remain for the student mere names to be got up by rote without any corresponding idea of their construction or action. The cause of the varying swiftness of the current of blood in arteries of different calibre and under diverse conditions would have been more useful to the learner. The statements made in the several sections are correct though necessarily brief, and the volume will be found serviceable to the student during his first year of attendance on lectures and as an introduction to larger works.

An Index of Symptoms as a Clue to Diagnosis. By R. W. LEFTWICH, M.D. Aberd. Second edition. London: Smith, Elder, and Co. 1901. Pp. 278. Price 6*s.*—We are glad to see that a new edition of this useful little book has been supplied, and we see no reason to alter the favourable opinion which we expressed in these columns[1] as to the first edition. It undoubtedly is a most useful compilation, but, as in all compilations written by those who know for those who do not know, there are omissions to be found. For instance, under the head of "Jaundice" we find no mention of morbus cordis as a disease of which jaundice is a symptom. True, we see that Dr. Leftwich mentions "cyanotic liver," and this in its turn is most commonly due to morbus cordis. Again, under the head of "Rigors or Shivering Fits," paroxysmal hæmoglobinuria is not given, though an attack frequently commences with a most violent rigor. However, it is next door to impossible to write a book of this kind without making some omissions, and taken as a whole the book is wonderfully complete. The chapter on "Methods of Diagnosis" is particularly good, and Section 1018 should be in every practitioner's mind. It deals with the Fallacy of Perspective, by which the old general practitioner is apt to assume that his patient suffers from some common disorder while the advanced *student* and the junior consultant assume that he suffers from a rare disease.

---

[1] THE LANCET, August 4th, 1883, p. 212.

Mentone as a Health and Pleasure Resort. By D. W. Samways, M.A., M.D. Cantab. London: Bemrose and Sons, Limited. 1901. Pp. 104. Price 3*s.* 6*d.*—Dr. Samways confesses in his preface that there have been innumerable books written about the Riviera. During the last 30 years, however, few have been published owing possibly to the fact that in the case of visitors to that favoured land "the inclination to record their experiences and professions has died out under the soothing influence of the comfortable modesty which fears to attempt a task which others might better have done." His own book he wishes to be taken as an effort to overcome the undue domination of such modesty. Mentone, we think, needs no advertisement, and probably it was a much nicer place 30 years ago than now—that is to say, for people who like quiet combined with lovely scenery and sunshine. The two latter are still there, but probably most of the quiet has departed. In one important point the increase in size has been a benefit—namely, in improved sanitation. Anybody, however, about to visit Mentone will do well to read Dr. Samways's little book, for in it he will find a variety of information about a very charming place, and we are glad to find that the book commences with an interesting summary of the history of Mentone. The municipality has set an example which is to be commended to all municipalities. Within the limits of the commune neither piano-organs nor beggars are allowed. Would that London were so blessed. The book contains neither index nor table of contents, omissions which might be rectified in a future edition.

Service des Enfants Trouvés de Notre-Dame de Péra. By Dr. Spiridion C. Zavitziano. Constantinople: The Annuaire Oriental and Printing Company, Limited. 1901. Pp. 139.—Dr. Zavitziano, who holds a prominent position among the medical profession in Constantinople, has very decided views as to the up-bringing of children who have ceased to be under the protection of their parents and who have for some reason or other been transferred to the care of public authorities. He strongly opposes the practice of aggregating these children in large institutions of any kind, such as schools, asylums, hospices, or whatever name they may be called by, and he maintains that in default of parental care the only hope for these waifs lies in a system of boarding-out (*placement familial*); in the case of young infants the foster-mothers must be wet-nurses. He has had many years' experience of this work, for since 1889 he has been in medical charge of the foundlings maintained by the Greek Church of Notre-Dame in Pera, and in the present treatise, which is dedicated to the memory of his father, Constantine Zavitziano, a teacher in the Académie Guilford in Corfu, he gives full details of the methods adopted. From June, 1889, to the end of 1900 the number of children who came under his observation was 344 and his statistics show a mortality that compares very favourably with the mortality among foundlings in some other places.

The Law of Bills, Notes, Cheques, and I.O.U.'s. By James Walter Smith, Esq., LL.D. London: Effingham Wilson. 1901. Pp. 172 and Index. Price 1*s.* 6*d.*—This is one of Mr. Effingham Wilson's excellent series of Legal Handy Books and is a clear statement of the matters mentioned in the heading. It is a legal maxim that ignorance of the law is no excuse and it is therefore just as well for the average man to have some knowledge of the law dealing with exchange of money. This little book will help him to such knowledge.

Cordingley's Dictionary of Stock Exchange Terms. By W. G. Cordingley. London: Effingham Wilson. 1901. Pp. 96. Price 2*s.* 6*d.*—Stock Exchange terms are of necessity somewhat of a mystery to those who have not been admitted to the arcana of the "House," but Mr. Cordingley's work clears up the meaning of such terms as Bull, Bear, Contango, Grangers, and the like. We also find explanations of the meaning of Coras, Doras, Floras, and Noras, and we can imagine the Stock Exchange Musical Society having on its programmes a song with a chorus of "My Coras, My Noras," on the lines of Eugene Stratton's "Susie, my Toosie." On page 42, *sub. voc.* Floras, we find the following: "A term used ... . for the Three per Cent. Preferred Converted Ordinary Stock of the Caledonian Railway to distinguish them from 'Noras' which is used to represent the Deferred Converted Ordinary Stock." "Noras" is evidently a misprint for "Coras." We do not find, moreover, any explanation of the term "Agio," which is possibly not now used on the Stock Exchange, although it will be in the recollection of readers of "Vanity Fair" that poor old John Sedley after his failure used to talk in the dreary coffee-house about "agios and Rothchilds and Baring Brothers."

The Revised Twentieth Century Phrenology. By John William Taylor. Morecambe: J. W. and G. Taylor. London: L. N. Fowler and Co. Pp. 250. Price 3*s.* 6*d.*—This is a book which, according to an advertisement slip which we found within it, is "One of the Greatest Achievements of the Nineteenth Century!!!" We are glad to be told this, for we should never have thought it. Phrenology is a "science" in which we cannot believe. We wonder whether Mr. Taylor amongst other beliefs holds that the inhabitants of these islands are the Ten Lost Tribes? We are led to ask this, for on page 82 we find the following: "We are under no more obligation to teach the doctrine of *combativeness, destructiveness*, and so forth, because our predecessors believed in them than we are bound to eat grasshoppers, beetles, &c., because our Jewish ancestors feasted on these insects."

The A-1 Cookery-book. By "H. N. L." London: Simpkin, Marshall, Hamilton, Kent, and Co. 1901. Pp. 172. Price 2*s.* 6*d.*—Of cookery-books there seems to be no end, but there is no doubt that good cookery is conducive to good temper and therefore to good health. "H. N. L." has produced an admirable work so far as it goes. She does not profess to teach the higher branches, but her recipes are sensible, and if—it is a great "if"—a cook will only follow them by the light of common sense the result will generally be good. "H. N. L.," however, takes too much for granted—e.g., in her recipe for dry curry she talks airily about "one or two fowls, or rabbits, or pork, or any other tender meat." Now fowls and rabbits vary in size. For this dish she recommends a tablespoonful of curry powder. In the recipe for ordinary curry she lays down three tablespoonfuls of powder for one pound of steak, while in the recipe for curry powder (p. 146) she again recommends one tablespoonful of powder to the pound of meat. These three recipes taken together are confusing. The recipe for curried veal, again, has a different set of proportional parts given, being further complicated by the introduction of curry paste. Apart, however, from these little inaccuracies the actual directions for cooking are sound.

The Literary Year-book and Bookman's Directory, 1901. Edited by Herbert Morrah. London: George Allen. 1901. Pp. 415. Price 3*s.* 6*d.*—The edition of this book of reference for 1901 is constructed upon the model of last year, but it is hinted that certain modifications are shortly to be made. We do not envy the editor if one of these modifications should turn out to be the application of any rigid principle of selection to the directory of authors. Exactly whom the title of author may comprehend must always be a matter of doubt. The Society of Authors recognise for admission to their roll all who have written a book, and though the number of persons thus qualified for the title is very large we do not see how any other limits can be laid down.

Consequently we may fairly expect to see the portion of the "Literary Year-book" which forms "A Directory of Authors" grow in size, and that to such an extent as to preclude any idea of adding to the writers' names the titles of their best known works. In the case of well-known authors such an innovation would be unnecessary; in the case of the rank and file of authorship the information would not be widely interesting. Of the introductory essays which form the first part of the book the most readable are the editor's preface and summary of the past year's work and an essay on the book sales of 1900 by Mr. Frank Rinder. An article upon literary agreements is ill-informed. The pitfalls of the commission system and the chicanery possible under the half-profit system are not properly revealed in it. The royalty which an author might fairly expect to receive under the royalty system goes unmentioned. This is the more surprising because the publication of books in general is apparently not being discussed under the royalty system, but only that of novels and books of short stories, concerning which there must surely be an accepted principle or, at least, an ideal price for the author to aim at and the publisher to give—or to resist. Moreover, it is incorrect to speak of "all self-respecting books—books, that is, issued at the publisher's risk." It may be that a novel nowadays has to be very bad before it fails to obtain publication by one or other of the numerous publishing houses; but novels are only a branch of literature, and not the most important branch by a long way. Much admirable serious work which can have, and can be expected to have, only a limited sale is not produced at the publisher's risk, as all scientific societies and scientific men know. The utility of a good book of reference is impaired by the dissemination of the fallacies contained in this article.

Analytical Records

FROM

THE LANCET LABORATORY.

PURE GRAPE BRANDY.

(WILSON AND VALDESPINO, LIMITED, 5, NEW LONDON-STREET, LONDON, E.C.)

WE have drawn the attention of the profession on previous occasions to the importance of employing genuine brandy—that is, a matured grape spirit—for medicinal purposes. Undoubtedly corn, maize, or other cereal spirit differs very materially therapeutically from grape spirit; and differential chemical analysis offers to some extent an explanation. Matured wine spirit invariably contains volatile compound ethers which have their origin in the fermentation of the grape. These ethers are absent in corn spirit. The curious ethers of wine not only exceed the stimulating effects of alcohol, but they impart that fragrance and bouquet which are the especial characteristics of cognac (fin champagne)—characteristics which are singularly missing in the so-called cognac brandies now upon the market. The falling off in the quality of French brandy has, of course, arisen from the destruction of vineyards in the environment of Cognac by the phylloxera and the consequent recourse to the distillation of foreign wines and the blending of the spirit obtained therefrom with spirit derived from some source which, whatever it may be, is not the grape. There is no reason now, however, why the French growers should not re-establish their great reputation, and already parcels of brandy from the Cognac district, we learn, are being exported which are the produce of the newly planted vine. But only time can be relied upon to make the production mature. In the meanwhile excellent grape spirit, and therefore true brandy, may be obtained from Spain, where, though the phylloxera has similarly made an appearance, it has not been on such a disastrous scale. The specimen of brandy before us is a product of the Spanish grape and very excellent brandy it is, recalling very closely, if not indistinguishably, the characters of real old cognac. It contains a complement of the ethers of wine, as will be seen from the following analysis: alcohol, by weight 45·55 per cent., by volume 53·24 per cent., equal to proof spirit 93·21 per cent.; extractives, 0·366 per cent.; acidity reckoned as acetic acid, 0·012 per cent.; ethers in terms of alcohol, 3·63 parts per 10,000. The amount of ethers attains the maximum compared with a great number of brandies that we have examined. The spirit is excellent in all respects and is mature, fragrant, and mellow. It is said to be 12 years old. It cannot be too widely known amongst medical men that excellent brandy of this type may be obtained which is infinitely better than a great deal of the French brandy now upon the market. The time has come, it seems to us, when the word "brandy" should have a definite legal meaning, applying exclusively to spirit distilled from grape spirit. The word "cognac" of course is not necessarily an assurance of grape spirit, for throughout Germany that word is applied to all "branntwein," which it is confessed has a very remote relationship, if any at all, to vintages.

(1) EXTRACT OF BEEF; AND (2) SOLUBLE BEEF.

(ARMOUR AND CO., 8 AND 9, KING-STREET, WEST SMITHFIELD, LONDON, E.C.)

The extract of beef gave on analysis the following results: moisture, 19·99 per cent.; mineral matter, 22·10 per cent.; and organic matter, 57·91 per cent. The total nitrogen was 8·05 per cent., which, employing the factor 6·25, would represent 50·87 per cent. of proteids. Treatment with alcohol, however, showed 11·44 per cent. of meat bases. Further examination showed the presence of acid albumins, albumose, and some peptone. The preparation makes a very palatable "tea" which is both appetising and nutritious. The soluble beef gave the following results on analysis: moisture, 23·53 per cent.; mineral matter, 17·09 per cent.; and organic matter, 59·38 per cent. The total nitrogen amounted to 8·85 per cent., which, multiplied by the factor 6·25, would yield 55·31 per cent. proteid, thus accounting, with the exception of 4 per cent., for the whole of the organic matter. Alcohol only extracted 1 per cent. of the organic matters. The preparation contains albumins and albumose but no important quantity of peptone. It contains the nutrient rather than the stimulant principles of beef. Both preparations afford a palatable soup or "tea" of fresh, beefy flavour.

ROYAL INSTITUTION.—The following are among the lecture arrangements at the Royal Institution after Easter: Dr. Allan Macfadyen, six lectures on Cellular Physiology, with special reference to the Enzymes and Ferments; Professor Dewar, three lectures on the Chemistry of Carbon; Professor J. B. Farmer, two lectures on the Biological Characters of Epiphytic Plants; and Mr. J. Y. Buchanan, three lectures on Climate, its Causes and Effects. The Friday evening meetings will be resumed on April 19th when a discourse will be delivered by Professor J. J. Thomson on the Existence of Bodies Smaller than Atoms.

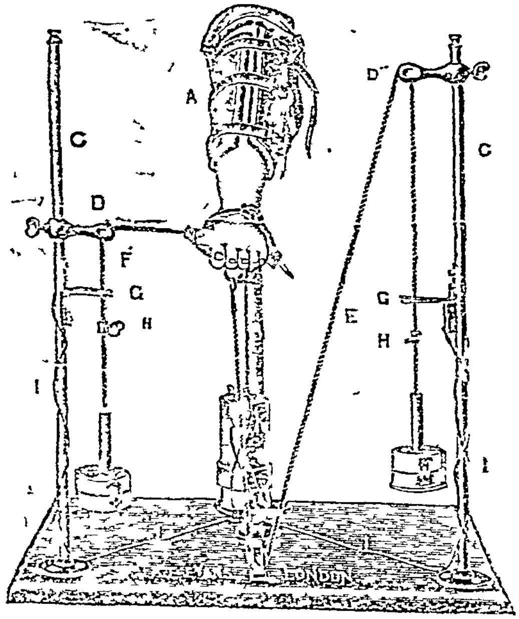
PORTHCAWL CONVALESCENT HOME.—The annual meeting of the subscribers to this institution was held on March 19th under the presidency of the Bishop of Llandaff. The report stated that 795 patients had been admitted during 1900, including 28 children, being 78 more than in 1899. The average number of days each patient remained in the home was 17 and the total cost for each, including salaries and general expenditure, amounted to 16*s.* 2*d.* per week. The new children's wing was opened last August at a cost of £2910.

New Inventions.

A MACHINE FOR APPLYING "RESISTANCE" EXERCISES IN DEFORMITIES OF THE FEET AND ANKLES.

I HAVE found the apparatus which is shown in the accompanying figure to be of great use in the treatment of all those conditions of the foot and ankle in which it may be desirable to strengthen any muscle or group of muscles, as in all forms of talipes and in flat foot and in-ankle. The apparatus consists of a padded trough A (supported by a pedestal B) in which the thigh and knee of the patient are securely strapped. Two side-pillars C, C, carry pulleys D, D, which can be shifted up and down as necessary and over which run cords E and F, each of which is attached to a weight W at one end and fastened at the other end to a strap which goes round the fore part of the patient's foot. In cases of varus or valgus in which it is desired to strengthen the abductors or adductors respectively, only one pulley and cord and weight are employed. That to the inner side of the foot is used for varus and that to the outer side for valgus. A third pulley fixed to the base-board of the apparatus is used for equinus when it is desired to strengthen the dorsi-flexor muscles of the ankle.

As it is difficult to induce young children to carry out these exercises, which they do not find amusing in themselves, I have added a dry cell K, and an ordinary electric bell with insulated wire circuits I, I, to the two side pillars.



Each circuit is broken at the metal contact-makers G, G, which take the place of the familiar bell-push. When the weight is lifted, G, G are acted upon by the adjustable stops H, H, which press the leaves of the contact-makers together and close the circuit, whereupon the bell rings and continues to ring until the weight is allowed to fall. The temptation to ring the bell and to keep it sounding at will is one which few children can resist and it becomes a treat to be allowed to use the exerciser. It is employed as follows. The patient is seated on a chair contiguous to the thigh-piece and the thigh and knee are securely fixed. The strap is secured round the front of the foot and the appropriate cord is fastened to it. The screw on the stop H is loosened and the stop is slid upon the cord until it reaches the desired spot where it is fixed. This should be in such a position that it will press against the contact-maker G, when the weight is lifted high enough and the desired amount of movement is done. In the figure the cord F is arranged as for a case of varus, while the cord E is arranged as for the treatment of equinus. If it be desired to use the machine to strengthen the calf muscles, as in a case of talipes calcaneus, both cords are to be used and both side pulleys raised up as high as they will go, but the middle pulley on the base-board is of course not used. It is in cases of congenital talipes and in flat foot that this exerciser is most useful. In infantile paralysis it is only useful to strengthen any muscles which are not palsied completely but only paretic.

The apparatus is well made and is supplied at a reasonable price by Mr. Albert Evans of Oakley-crescent, City-road, London, E.C.

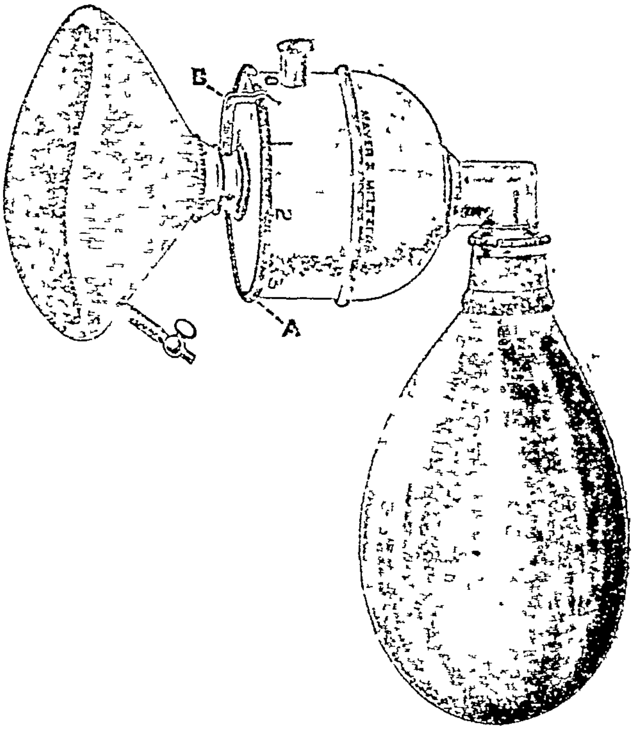
E. MUIRHEAD LITTLE, F.R.C.S. Eng.,
Surgeon to the National Orthopædic Hospital, London.

A HOSPITAL CHART.

WE have received from Messrs. Reynolds and Branson, Briggate, Leeds, a form of chart which has been in use in Dr. T. Churton's ward in the Leeds General Infirmary for two years. It shows the pulse and respiration rates in the same space by means of dots and connecting lines for the pulse and crosses for the respiration rate. The proportional figures (pulse : respiration as 4 : 1) are in parallel columns, so that an abnormal proportion is detected at a glance. The chief use of the chart is the instantaneous perception of the ratio existing between the temperature, the pulse, and the respiration. Spaces for recording the quantity and the specific gravity of the urine, and particulars of diet and drugs are ruled at the foot of the chart. With these additions its dimensions are eight inches by 10½ inches.

A MODIFIED CLOVER'S INHALER.

MANY who have been accustomed to administer ether with the ordinary Clover's inhaler will have had some experience of the inconvenient tendency which the reservoir has to become separated from the face-piece during administration. This is especially liable to occur when for some reason the patient has to assume the lateral or semi-prone position. I have had a slight modification made in the apparatus which prevents this detachment taking place. A projecting rim A is fixed round the lower margin of the reservoir. In this rim there is a slit opposite the O through which the upright portion of the indicator B passes. This portion of the indicator is curved so that it hooks over the rim as soon as the reservoir is turned on the face-piece. The reservoir is thus firmly fixed and cannot be separated from the face-piece until the indicator again points to O. The modification has been carried out for me by Messrs. Mayer and Meltzer of Great Portland-street, W., and can be adapted to the ordinary apparatus at a small cost.



CHARLES HERBERT THOMPSON, M.D. Dub.,
New Cavendish-street, W. M.R.C.P. Lond.

THE LANCET.

LONDON. SATURDAY, APRIL 6, 1901.

The English Census.

THE eleventh census of England and Wales has just been taken. For the last nine months active preparations with this object in view have been in progress at Somerset House, and so far as the mere counting of heads is concerned the procedure was practically completed on the evening of Monday last The alarm with which the earlier proposals to number the people of England were received by them and by Parliament has in these later days well nigh subsided under the influence of education. At the opening of the twentieth century we are not called upon to allay the fears which prevailed very generally a century since to the effect that an enumeration would be used as a basis for new taxation or even for conscription, or, worse still, that the numbering of the people would betray the inability of England to furnish a due supply of soldiers and sailors for the protection of our native land Neither are we asked nowadays to combat the opposite form of alarm—namely, that the people are increasing so rapidly as to outstrip the means of subsistence. With few exceptions people have at length come to realise the fact that they are not counted every ten years out of idle curiosity, but in order that the Government of the country may be carried on and laws framed according to indications which can only be known when the population of the various districts has been accurately determined. During the last few weeks the public have been carefully instructed through the agency of the daily press, and apparently from official sources, concerning the purposes for which a national census is required, and quite recently the Registrar General has published an appeal to the heads of families throughout the country for their assistance in rendering the present census as correct as circumstances will allow So that we may look forward to the census of 1901 being especially valuable because the returns are likely to be more reliable than any similar returns previously made

To our own profession, and especially to that branch of it which is engaged in the study and practice of State medicine, the accurate taking of a census is a matter of the very highest importance That this is the case will readily appear from the following considerations. In the first place, population is the only basis upon which rates of birth, sickness, and death can be calculated. England and Wales have been parcelled out into administrative sanitary areas, both urban and rural, over which areas elective boards are appointed with definite powers and responsibilities It is essential for the due performance of their statutory duties that these authorities should possess the means of measuring with a near approach to accuracy the prevalence from time to time of preventable sickness and also of mortality in the several areas within their jurisdiction. The Local Government Board, as regards particularly interested in securing an accurate return of the numbers living in the various (some 2000) sanitary areas of England and Wales, as well as in the registration districts and sub districts, which are more numerous still. The supervisory duties of the Board under the Vaccination Acts must be much lightened by an appreciation of the figures to be dealt with That the returns of the census should be as accurate as possible is matter of scarcely less concern to the Factory Department of the Board of Trade which, under the able guidance of a medical chief, is now doing admirable sanitary work among the workers in factories and workshops throughout the country. To that department it is essential that the fluctuations of the population engaged in certain injurious or dangerous trades should be accurately known between one census and another. The uses to which Dr WHITELEGGE has applied even the scanty information of this kind hitherto at his disposal will be appreciated by those who are familiar with the highly instructive reports for the last few years of the Chief Inspector of Factories

The recent extension to the country generally of the Act for the compulsory notification of certain dangerous infectious diseases is a cogent reason why the population of the various administrative areas concerned should be ascertained with great precision and even with greater precision than is possible with the help of only a decennial census A return to a sanitary authority or to the Local Government Board to the effect that a certain number of cases of some epidemic disease—say, of diphtheria—had occurred in a given district within a stated period of time would be meaningless without the complementary statement of population which alone enables us to form a judgment of the proportional prevalence of the disease And if the population is incorrectly estimated the ratio of sickness will, of course, be equally incorrect In point of fact, this recent extension of a most valuable sanitary enactment furnishes a strong argument for the establishment of a quinquennial census for England and Wales at least as complete as that now obtaining in the metropolis All competent authorities are agreed as to the necessity of a numbering of the people once in every five years, and there are many reasons for wishing that in the year 1906 the quinquennial census of London should be extended to the remainder of England and Wales

The Ethnological Significance of Burial Rites.

IT is well known that the excavations of M DE MORGAN and Professor FLINDERS PETRIE in the prehistoric cemeteries of Egypt are believed to have shown that one or more new primitive races inhabited the Nile valley of different ethnological relationship to the people we ordinarily speak of as the ancient Egyptians The reason for considering that these more lately discovered relics indicated new or alien races was the completely divergent method of sepulture, for in these extremely ancient interments, instead of the bodies being carefully preserved by mummification, they were deposited in three different manners, all apparently entirely opposed to mummification.

In one of these the skeleton was found with the knees drawn back to the sternum, the hands pressed to the face, and the whole skeleton compressed into the smallest possible dimensions and placed in a trench in the desert sand; in a second the skulls were removed from the spinal column, and the complete set of bones of one or more persons, bearing traces of having been scraped to remove the flesh and of having been submitted to some process tending to preserve them, were carefully packed together in a tomb; and in a third the body—perhaps the skeleton only—had been burnt together with some of the funeral offerings. These systems of sepulture, apparently so contrary to mummification as to indicate an entirely different race of people, have now been instanced by M. BAILLET, in an article in the Journal of the French Archæological School at Cairo, as proving a similar idea for the preservation of the defunct to that which later produced the perfection of mummification as known to the historic Egyptians.

M. BAILLET'S method of reasoning, based entirely upon the statements of the most ancient and therefore least corrupted religious texts, is well founded and is interesting to all studying the history of mankind. M. BAILLET, after considering the three prehistoric burial systems, concludes that the methods of all were produced by the pre eminent desire to preserve and to perpetuate as far as possible the remains of the defunct. In the first case the placing of the compressed skeleton, after removal of the flesh, in the smallest possible compass in the desert sand, in some cases after anointing the bones with bitumen or such like substances, tended to prevent the remains from being disturbed by beasts of prey who would have sought it for the flesh. In the second case, where the bones were separated, the object in view was the same, only more fully carried out. The skeleton having been broken up more entirely to remove all particles of flesh and sinew, the interior contents of the skull, which might have given rise to putrefaction and hastened the decay of the bones, were got rid of, and the bones completely anointed or filled with bitumen or resinous substances. In the third case he points out that the incineration did not take place upon a funeral pyre in the open air, in which case the remains would have been dispersed and lost, but in a confined tomb where the ashes remained carefully preserved as long as the sepulchre remained intact. At this point it may be noted that mummification itself was not really a preservation of the flesh of the deceased but practically a removal of parts and a desiccation of parts, for, as HERODOTUS tells us, in its perfect attainment the result achieved was the dispersion of the flesh, leaving practically nothing but skin and bones. As is well known, all the viscera as well as the contents of the skull were removed as preliminaries to embalmment because of the increased tendency to putrefaction if they remained, and the Egyptian rituals for mummification themselves state distinctly that it was to prevent putrefaction that the process was carried out. The great sacred work known as the "Book of the Dead" also shows this: chapter 14 is entitled "That the body may not be corruptible"; chapter 71 is entitled "To repulse corruption"; chapter 173 is entitled "To prevent any damage to the corpse and to preserve the flesh and bones"; chapter 154 treats "of preventing the decomposition of the corpse." Beyond this texts in the "Book of the Dead" tell that by mummification more of the cadaver is to be preserved than formerly, thus indicating a recollection of the inferior, more primitive processes and showing the advance that had taken place in the art of mummification. The second book speaks of the deceased as arriving in the next world having had his flesh embalmed so that his actual body will not decay, "*his companions have put aside his flesh*; his flesh will not become evil"; and again addressing the defunct it says, "Thy flesh accompanies thee, there is no corruption for thee, no vermin; thy head and neck have not been broken; thy tongue has not been removed nor thine eyebrows shaved; no evil has been performed upon thy cadaver which shall not now perish." The expression in italics is quite contrary to the assertion as to the preservation of the flesh, from which M. BAILLET argues that it is a piece of a rubric of the older version of the text when the flesh was removed and the skull and the bones were separated, and that the scribe, not understanding its meaning, had permitted it to remain part of the volume which vaunted that these acts had been dispensed with. Many texts show that the Egyptians attributed their success in at length preserving the semblance of the body by mummification to the use of baths and unguents which dissolved or dried up the decomposable constituents, and also to their marvellous system of bandaging with wrappings prepared with certain preservative solutions. To the populace the priests gave out that the flesh of the departed was preserved, but to the initiated it was known that the majority of its constituents were dissipated by the processes which it underwent, hence in the same inscriptions upon the tomb pyramid of PEPI we have such apparently contradictory assertions as "the bones of PEPI are as of iron, the flesh of PEPI as the indestructible stars," and again, "deliver the defunct from the flesh that was in him."

All the funeral processes of Pharaonic times had but one object—to insure the non-decomposition or purity of the body, because by that means, it was imagined, only could the spirit's existence be perpetuated. The incense and natron offerings, fumigations, and libations at the annual funeral feasts were all but copies of the provisions that had been made after death for the preservation of the corpse and were intended annually to renew their efficacy. Even the sarcophagus was but a replica of the great natron bath in which the body had been steeped. Before these means of obtaining the object of preservation had been perfected the dryness of the desert sand had been relied on and the body had been compressed to preserve its form intact. Then preservation had been attempted by cutting or burning the tissues away, the remnants being carefully anointed and covered with resin or bitumen. In course of time a way was invented of destroying the corruptible matter without damaging the external form. The skull was embalmed through a fracture in the ethmoid bone instead of being decapitated. The viscera were removed to prevent decay, but were placed in four canopic vases in the tomb. The flesh withered away beneath the skin which was protected by bandages, the thickness of which restored apparently the proper proportions of the body. All through the ages of Egyptian history the aim of funeral rites was similar, so that the procedures may have been the actions of but one single people, that mysterious race of which Professor OWEN concluded that they may have been autochthones of the Nile valley

A Case for Publicity.

THE financial position of most of the London hospitals is as a rule insecure That is to say, the funded property produces far less income than is required to meet the expenses to which the institution is yearly put, and the balance has to be defrayed by voluntary contributions, reaching the charity either directly from subscribers and testators, or indirectly in the shape of grants from funds such as the Metropolitan Hospital Sunday Fund, the Hospital Saturday Fund, and the Prince of Wales's Hospital Fund for London Moreover, as the population of London increases the stress put upon the hospitals becomes greater, while the lists of subscribers do not lengthen in proportion This being so it is of the utmost importance that a hospital should not dispose of any valuable property which it may possess, particularly if that property is of a nature that is bound to appreciate, without very full and free discussion having taken place upon the matter

We are led to these remarks by three letters which have recently appeared in our columns—namely, one from "A Governor of the Hospital," which was published in THE LANCET of March 9th, p 739, another from "Hospital Governor," in THE LANCET of March 23rd, p 893, both dealing with the affairs of the Royal Orthopædic Hospital, and a third in THE LANCET of March 30th, p 971, from the secretary to that institution This hospital, as may be known to some of our readers, occupies a very valuable site, having a frontage both to Oxford street and to Hanover-square The site is the freehold property of the charity It appears that the Managers of the Prince of Wales's Hospital Fund for London at one time recommended the sale of the site, and the committee of the hospital in June, 1899, having the same view, wished to sell the property for the sum of £28,000 The subscribers to the charity, however, disagreed with the committee, who were defeated upon the question being put to the vote mainly by the efforts of Mr H H. MARKS, the present chairman of the hospital Mr MARKS, it is alleged, acknowledged that he obtained his majority by votes specially created for the purpose of resisting the scheme for selling the site of the hospital The committee accordingly resigned and a new committee was formed with Mr MARKS as chairman This committee, at a meeting held on Feb 18th, 1901, received full permission to sell the site and to buy another A description of the meeting will be found in THE LANCET of Feb 23rd, p 591 On March 14th a meeting of the committee was held at which, according to the letter from "Hospital Governor," an offer of £37,700 for the site was brought forward without previous notice. "Hospital Governor" gives an account of the meeting the accuracy of which is challenged by the secretary of the hospital The secretary does not state in detail with what statement he finds fault, but we do not understand that the essential fact that it has been voted by the committee to accept the offer of £37,700 is denied Now £37,700 represents £1300 at 29 years' purchase and is a good price to obtain for land in most places But Oxford street and Hanover square afford positions of simply incalculable value At the meeting on Feb 18th it was said that the value of the site was £45,000, or £1500 at 30 years' purchase, and every decade the property will continue to rise in value—if precedent is to be relied on in the least Mr MARKS's position requires explanation Having as we understand admittedly, turned out a committee which was preparing to sell the site of the hospital for £28 000, he is now, as chairman of the committee, ready to sell that site at £7300 below a valuation which has been attributed to himself, and that without bringing forward any reasons to show why the sale is necessary at all For surely an asset of increasing value should not be sold without an urgent reason Something must have occurred to change Mr MARKS's mind, for quite recently, we believe, the hospital was put into thorough sanitary repair at a cost of some £2000, an expense that surely would not have been incurred if it was intended to evacuate the building in a few months.

We are in no way wishful to dictate to the hospital authorities how they should dispose of their property, but we think that without doubt the matter deserves thorough ventilation and that the disposal of such a valuable site should not be decided upon hastily It may not be necessary, or even financially sound, for a charitable institution to occupy a site which so far as either frontage is concerned might be filled by first-class business premises, but surely it is the duty of those responsible for the administration of the charity to see that a good bargain is made if the premises are vacated We do not know where the authorities propose to obtain their new site but presumably it would be somewhere where land is less expensive Surely this could be managed without the sale of their valuable freehold by borrowing money, even if it is deemed advisable to leave the building with which they have been long associated and upon the sanitary needs of which they have just spent a large sum We cannot see that there is any hurry in the matter The committee are not pressed for time in their anxiety to catch the top of the market, for freehold property in Oxford-street is not in the least likely to go down in value, while the offer which they are preparing to accept is 15 per cent below the sum which has been estimated as the right sum "Hospital Governor" says that an offer has been made to lease the Hanover square end of the property at £1200 a year If this is so, why have not this and similar alternatives been discussed? Discussion is all that is wanted The committee are acting, it is understood, in accordance with the views of the Prince of Wales's Hospital Fund for London The public has a right to know upon what those views are founded, for it is the public who will be painfully pleaded with to find the income if the Royal Orthopædic Hospital squanders its capital The secretary of the hospital protests against the premature discussion in the press of business under conduct by hospital committees We join in the protest, only asking, When is discussion premature? Surely it will be too late for practical purposes to debate the policy of selling the site of the hospital after the sale has been effected

Annotations.

"Ne quid nimis."

STATE LUNATIC ASYLUMS IN INDIA.

THE Secretary of State for India has sanctioned a scheme for five large central asylums for the insane in India. Hitherto in India there have been only a number of small asylums under the care of the civil surgeons of the stations where they were situated, who make, of course, no claim to special familiarity with psychological medicine, and whose time is fully occupied by the ordinary claims of their position. We trust that men of proved knowledge in psychological medicine will be appointed to the superintendence of these asylums; and that it is the intention of the Government to attract suitable candidates is shown by the fact that special rates of pay are to be given. The salaries will range from 600 to 1400 rupees per month, so that the pay will be about 50 per cent. higher than full regimental pay in the Indian Medical Service, with a house thrown in and leave to conduct a private consulting practice. The appointments will be open to, though not restricted to, officers of the Indian Medical Service, but inasmuch as a knowledge of native language and customs will be of immense value to the superintendents of the new asylums it is probable that the appointments will fall to members of the Indian Medical Service who can prove their fitness for the berths. The existence of highly-paid scientific appointments like these should induce young men with a taste for psychological medicine to enter the service and those who have had the practical experience of a sojourn of a year or two in a first-class asylum at home should have a strong claim for an appointment. As time goes on the number of these asylums will probably increase and they may become valuable clinical centres, for in India at the present moment there is not a single private asylum or any facility for learning psychological medicine. The five new asylums will be situated at Bishanpur for Bengal, at Agra for the North-West Provinces, at Lahore for the Punjab, at Poonah for Bombay, and at Madras. The asylum at Lahore has been completed, that at Agra is under construction, while the existing buildings at Madras, which are very good, will be utilised.

MEDICAL AND SURGICAL APPOINTMENTS TO THE KING.

A FURTHER list of medical and surgical appointments to the King appears in the *London Gazette* of March 29th:—To be Physicians in Ordinary to His Majesty: Sir William Henry Broadbent, Bart., K.C.V.O.; Sir James Reid, Bart., G.C.V.O., K.C.B.; and Sir Francis Laking, K.C.V.O. To be Physicians Extraordinary to His Majesty: Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I.; Sir Richard Douglas Powell, Bart., K.C.V.O.; Sir Edward H. Sieveking, Sir Felix Semon, and Dr. John Lowe. To be Physician to His Majesty's Household: Sir Thomas Barlow, Bart., K.C.V.O. To be Honorary Serjeant-Surgeon to His Majesty: Mr. Frederick Treves, M.V.O. To be Honorary Surgeons in Ordinary to His Majesty: Mr. Thomas Bryant, Mr. Alfred Downing Fripp, M.V.O., and Mr. Rickman John Godlee. To be Surgeon to His Majesty's Household: Mr. Herbert William Allingham. To be Surgeon-Apothecary to His Majesty and Apothecary to His Majesty's Household: Sir Francis Laking, K.C.V.O. To be Honorary Surgeon-Oculist to His Majesty: Mr. George Anderson Critchett. To be Honorary Surgeon-Dentist to His Majesty: Mr. Henry Bell Longhurst. To be Dentist to His Majesty's Household: Mr. Edwin Thomas Truman. To be Honorary Anæsthetist to His Majesty: Dr. Frederick William Hewitt. To be Chemist and Druggist to His Majesty: Mr. Peter Wyatt Squire. To be Surgeons-Apothecary to His Majesty's Household at Windsor: Mr. William Fairbank and Dr. William A. Ellison, jointly. To be Surgeon-Apothecary to His Majesty's Household at Sandringham: Dr. Alan Reeve Manby, M.V.O. To be Honorary Physicians in Ordinary to His Majesty in Scotland: Sir William Tennant Gairdner, K.C.B., and Dr. George William Balfour. To be Honorary Surgeons to His Majesty in Scotland: Dr. Patrick Heron Watson and Dr. Alexander Ogston. To be Honorary Surgeon-Oculist to His Majesty in Scotland: Dr. Douglas Argyll Robertson. To be Physicians in Ordinary to His Majesty in Ireland: Sir John Thomas Banks, K.C.B., and Dr. William Moore. To be Honorary Surgeons to His Majesty in Ireland: Sir Philip Crampton Smyly and Sir William Thomson. To be Honorary Surgeon-Oculist to His Majesty in Ireland: Dr. Charles Edward Fitzgerald. It will be remembered that in our issue of March 2nd we published the following list:—To be Sergeant-Surgeon in Ordinary to His Majesty: Lord Lister. To be Honorary Sergeant-Surgeons to His Majesty: Sir William MacCormac, Bart., K.C.V.O., and Sir Thomas Smith, Bart. To be Honorary Physicians: Dr. D. McEwan, Inspector-General (retired); Sir James J. L. Donnet, K.C.B., Inspector-General of Hospitals and Fleets; Sir John Watt Reid, K.C.B., Director-General of the Medical Department of the Navy (retired); Dr. A. B. Messer, Inspector-General of Hospitals and Fleets (retired); Dr. H. C. Woods, M.V.O., Inspector-General of Hospitals and Fleets. To be Honorary Surgeons: Sir James Jenkins, K.C.B., Inspector-General of Hospitals and Fleets; Mr. Timotheus J. Haran, Inspector-General of Hospitals and Fleets; Sir James N. Dick, K.C.B., Director-General of Medical Department of the Navy (retired); Dr. William H. Lloyd, Inspector-General of Hospitals and Fleets; and Dr. Alfred G. Delmege, M.V.O., Deputy Inspector-General of Hospitals and Fleets. This, we believe, completes the list. Many of these gentlemen have previously held similar appointments either to the King (when Prince of Wales) or to her late Majesty Queen Victoria, while some of the appointments are new. The position of Honorary Anæsthetist to His Majesty, which has been given to Dr. Hewitt, is, we believe, an entirely new office created by His Majesty.

THE SCIENTIFIC PRODUCTION OF MILK ON A LARGE SCALE.

WE have already alluded to the satisfactory steps which are being taken in this country by large dairy companies to supply not only pure and sterile milk but milk also standardised for special purposes. Milk as a source of disease is well known and its chief danger is its extreme liability to become infected with the tubercle bacillus. The conditions under which the production of milk is carried on are gradually passing from the old rule-of-thumb method to the scientific methods of the present day. This change, it may be remarked, does not only secure the production of milk of a non-infective character but it has also brought greater economy into the methods and results. One of the largest examples of an enormous milk-supplying station in which the production of milk is dealt with scientifically on the score both of hygiene and economy is the establishment of Herr C. Bolle in Berlin. From particulars recently furnished to us by Sir Otto Jaffe, who has studied the question of milk-supply in a number of towns at home and abroad, we learn that Herr Bolle started his business in the year 1871 when he distributed 500,000 gallons of milk, whereas at the present day he supplies milk at the rate of 7,000,000 gallons to about 50,000 families. The milk is all sent out from one central station. The firm supply milk, cream, milk from a special farm for infants, sterilised milk, kefyr, machine-skimmed milk, butter-milk, butter, and cream cheese In this great central station there are a bacteriological laboratory, a chemical analytical laboratory, and a chemical technical laboratory. In 1899 over 30,000 tests were made in the chemical analytical laboratory alone, and over 1500 guinea pigs were used in the bacteriological laboratory, mostly for tests of tuberculosis In the chemical technical laboratory experiments are made upon the by-products of milk which are utilised. Special officers are retained for supervising the 130 farms with their 14,000 cows which supply the central establishment, and the duty of controlling and observing the health of the cows is in the hands of four veterinary surgeons. Till a few months ago the firm passed the greater part of the milk which they collected from the various farms through filters of sterilised gravel which freed the milk of many of its impurities, destroyed many micro-organisms, and tended to keep the milk sweet. Within the last few months, however, they have made arrangements for using an improved Pasteurising process for the whole of the milk which they receive with the exception of that which comes from one of their own farms, and they consider this to be one of the most important improvements that they have adopted since the opening of their establishment They maintain that this process interferes neither with the taste nor with the chemical composition of the milk, but destroys any pathogenic microbes such as those of diphtheria, scarlet fever, typhus fever, and particularly tuberculosis. The entire establishment, which includes butter, cream, and cheese manufacture on similarly scientific lines, covers more than five and a half acres The steam engines develop about 400 horse power. The cooling plant is able to produce about 20 tons of ice a day. It is stated that the rapid growth of this industry has been accompanied with an excellent effect upon the general milk-supply of Berlin; in 1879 14 1 per 1000 of the samples investigated by the police authorities were adulterated and in 1886 only 3 6 per 1000 The infant mortality per 100 living born children in 1871 was 30; this fell in the next 10 years to 27 1 and in 1899 it fell to 23·4 Even if it is also admitted that many other influences have contributed to the decrease of infant mortality undoubtedly the improved milk supply has had much to do with it The facts speak eloquently in favour of the scientific preparation and supply of milk and milk products

THE SALE OF "DRINK" TO CHILDREN.

MR CROMBIE spoke truly when he stated that his Bill to prevent the Sale of Intoxicating Liquors to Children has the approval of the country. The tendency of popular opinion with regard to this question has been frequently manifested in the press and on the platform Once more it has found emphatic expression in a vote on the second reading of this Bill passed by a substantial majority of 318, which represents the collective decision of all parties in the legislature. This measure, it may be added, is the result of no sudden movement of the national mind. A Royal Commission has already proved that the public house exercises a mischievous influence on young children sent thither to fetch liquor and that drinking habits are thus engendered even at so early an age The only argument adduced so far in favour of this practice appears to be that it suits the convenience of working parents The contention obviously rests on the slightest foundation The publican and the workman have under almost any circumstances an unequalled facility in accommodating one another. Convenience of this kind attends every hour of the working day and it acts too often as a serious impediment in the course of business Less of such convenience would prove rather a gain than otherwise In any case it cannot be allowed to stand as a reason why children—who, as Mr. Crombie reminded us, constitute the hope of the country in its international struggle for existence—should be contaminated by a ruinous habit at the very outset of life Amendments in committee may be looked for, but we trust that they will not be allowed to impair the vitality of this wholesome and useful measure

A MEDICAL MAN'S GENEROUS LEGACY.

THE Corporation of Portsmouth has just received under the will of the late Mr George Scale, a sum of £20,000 to provide annuities for the blind. Applicants must be over 30 years of age and necessitous The amount of each annuity is fixed at £30, so that at least 20 blind persons will benefit by Mr. Scale's bequest Mr. Scale was for many years, as was his father before him, a medical practitioner in Portsmouth where he practised in the Commercial road. The father died some 20 years ago and the son, who died recently, retired from practice in 1872 owing to blindness Since his retirement he has resided at Emsworth. He never recovered his sight but his bequest shows that he was ever mindful of those who were afflicted in a like manner

THE RICHMOND WATER-SUPPLY.

THE Town Council of Richmond, Surrey, have always been very anxious to have an independent water supply and they have taken a great deal of trouble and incurred great expense in the matter At the time of Lord Llandaff's Commission the council protested that their district ought not to be placed under any new body which might be entrusted to carry on the duties of managing the water supply of London Last year Mr. Mansergh was asked to make a report as to the nature of the existing works of the corporation and as to their efficiency, and he was further requested to make suggestions for the improvement or enlargement of the plant, and to recommend the best available method for increasing the supply of water The present works he found to consist of wells and of a brick tank situated in Petersham meadow Of the wells one is sunk through the London clay into the chalk which is reached at 254 feet below the surface From this well a boring which varies in size from two feet to seven inches passes downwards to a total depth of 1446 feet Another well which has a depth of 320 feet passes for 30 feet into the chalk. From the bottom of this well headings have been driven to the well previously described and in various other directions These headings are six feet in height, four feet six inches in width, and their total length amounts to no less than 10,400 feet In addition to this borings have also been made below the headings in many places where it was hoped that fissures might have been found In spite of all this work the quantity of water which has been obtained has not exceeded 260,000 gallons per day With a view to discover the cause of the deficiency of the water and to what extent the chalk in the district around was similarly depleted Mr Mansergh made a series of inquiries in regard to wells which existed in the neighbourhood. It was found that in the case of a well situated two miles to the north of Richmond the water level had sunk about 68 feet during the last 50 years In the case of another well three miles to the north east the level of the ground water had sunk 72 feet since the year 1877. Records were given of six wells and in every case the water-level had sunk to some extent. Mr. Mansergh gave it as his opinion that the cause of the lowering of the water-level at Richmond was due in part to the pumping which had taken place there; that from the chalk around also an excessive amount had been removed by pumping; and that the amount of the rainfall during the last few years had been insufficient to make good the amount taken. The supply from Petersham meadow is derived from a brick tank 15 feet in depth into which the water from the meadows is conducted by means of a double line of stoneware pipes which are laid open-jointed and covered with a layer of screened gravel and sand. The water from this source has been open to the suspicion of pollution and a specimen of it was therefore sent to Dr. Klein for analysis. Amongst other things his report stated that he found specimens of proteus vulgaris and bacillus coli. In summing up the results of his examination Dr. Klein said that the water was not in a satisfactory state and that it contained a fair number of microbes which must be considered as having been derived from the surface soil. According to a report in the *Thames Valley Times* of Feb. 13th, 1901, Dr. Klein, in answer to further questions which had been addressed to him by a member of the Richmond Town Council, said that even this water was better than that supplied by the Southwark and Vauxhall Water Company. The state of the water supplied from Petersham well has led Mr. Cockram of Richmond to address to us a series of letters with regard to the pollutions which he considers are a great source of danger in the water obtained from the meadows. We are informed that many anglers are accustomed to assemble on the banks of the Thames between Buccleuch House and Ham House, and that they spread decomposing animal and vegetable matter on the towpath and act generally in a manner which is liable to cause pollution to the surface of the meadow itself. It seems that this part of the bank of the Thames has a peculiar fascination for anglers, and the *Fishing Gazette* often contains somewhat long reports in regard to their proceedings. Prizes are given to the most successful anglers and occasionally their number is to be reckoned by hundreds of gentlemen who are stationed at intervals over a course of nearly three miles. An enormous number of prizes is given and we have been favoured with a list of those which were to be awarded as the result of a monster competition held towards the end of last year. On this occasion the *Fishing Gazette* stated that the rain was "almost intermittent," but we are not quite clear as to whether this was a favourable climatic condition for the sport. Angling has always been a favourite pursuit with a great many people who live in the East End and in other parts of London, and it is the only out-of-door recreation which is enjoyed by a very large number of people. It is an extremely good thing for them that they are able to obtain healthy amusement in this way at a very small cost, for the railway companies convey them at specially cheap rates. It is to be hoped that in future the anglers will take care not to do anything which may cause danger of pollution to the Petersham meadows, and we have no doubt that should our contemporary the *Fishing Gazette* point out to its readers the great hardship which some anglers have inflicted on the people of Richmond they will make arrangements which will obviate the possibility of any future annoyance.

THE NITROPROPIOL TEST FOR SUGAR.

In a recent number of the *Munchener Medicinische Wochenschrift*, Dr. Franz von Gebhardt of Budapest describes this test for sugar in the urine by means of orthonitrophenylpropionic acid. The reduction of this substance by sugar was pointed out by A. Baeyer in 1880.[1] Messrs. Teusch of Ehrenfeld, a suburb of Cologne, have for some time been supplying tablets in which orthonitrophenylpropionic acid is compressed with sodium carbonate. The test by means of these tablets was described in The Lancet of Feb. 17th, 1900, p. 471. According to these makers the method of testing for sugar is to dissolve a tablet in 10 cubic centimetres of water, add 10 drops of the saccharine solution or urine to be examined, and boil the whole gently for from three to four minutes. If sugar be present the entire solution assumes an indigo-blue colour, and, if it is allowed to stand, indigo insoluble in water separates out and collects at the bottom. At one of the clinics connected with Budapest University, Dr. von Gebhardt has for a considerable time used nitropropiol tablets in testing for sugar. Instead of following the method recommended by the manufacturers, he does not begin by dissolving the tablet, but he takes from 10 to 15 drops of the saccharine solution or urine to be examined, adds 10 cubic centimetres of distilled water, and then the tablet, and warms the whole gently for from two to four minutes. If sugar be present the solution becomes at first greenish and then dark indigo blue. Dilution of the saccharine solution keeps the reagent always in excess with respect to the sugar, otherwise the reduction with formation of indigo blue does not occur, but indigo white is formed instead and the solution remains colourless. If the proportion of sugar is very small the fluid to be examined need not be diluted. It often happens that the blue colour does not come out with sufficient clearness, in which case he adds chloroform and shakes; the chloroform takes up the indigo and forms a blue layer at the bottom. Dr. von Gebhardt has satisfied himself by many experiments that sugar is the only constituent of the urine that gives this blue reaction. The colouring matter of the bile, uric acid, albumin, blood, phosphates, kreatinin, and glyconic acid do not produce the effect. The reaction succeeds with saccharine urine in presence of minute amounts of albumin, pus, or blood, but the boiling must be longer than in the absence of these. If the proportion of albumin is larger it must be removed by shaking with chloride of sodium or chloroform before the application of the test. The following drugs taken by persons whose urine is free from sugar do not cause the urine to give the reaction: benzoic acid, chloral hydrate, carbolic acid, guaiacol, iodine, rhubarb, salicyl compounds, senna, and turpentine. As regards the sensitiveness of the reaction 30 milligrammes of dextrose dissolved in 100 grammes of water and not further diluted gave a blue colouration; 25 milligrammes in the same quantity of water gave a green colouration instead of blue; 50 milligrammes in the same quantity of water gave a reaction even when 10 drops of the solution were added to 10 cubic centimetres of water. Dr. von Gebhardt further points out that the reaction is simple, rapid, and inexpensive, that it requires no chemical except the tablets, and that it may be performed with only a few drops of urine.

THE BOSTON RURAL DISTRICT COUNCIL AND ITS MEDICAL OFFICER.

The position of a medical officer of health to a small district is not altogether a pleasant one. He is almost sure to come into conflict with sundry existing interests, that is to say, if he does his duty, and the owners of the said interests not unnaturally feel hurt. The Boston (Lincolnshire) Rural District Council held its monthly meeting on March 16th and decided by a majority of one vote to advertise for a medical officer, the term of appointment of the holder, Dr. Arthur Tuxford, expiring on March 25th. Mr. Clarke, who proposed that the post should be advertised, explained that he, with many more, was not satisfied with Dr. Tuxford, and Mr. Brown seconded the motion. Mr. Eley, however, moved as an amendment that Dr. Tuxford should be reappointed, and Canon Stafforth, in seconding the amendment, pointed out that although Dr. Tuxford's report was somewhat disheartening, yet it was better that they should know the truth as to health matters.

---

[1] Bericht der Chemischen Gesellschaft, xiii., 2260.

Mr. Eley pointed out that a medical man, if conscientious and sincere, was bound to make enemies. The council, [illegible] decided to advertise the post. It [illegible] the medical officer is the [illegible] of that document makes matters plain. We see that in the district of Skirbeck many houses drain into cesspools; others drain into sewers which open into a stagnant ditch by the roadside. Others, again, drain into "Bargate drain" which has numerous houses on its banks. We may here explain that "drain" in the fens does not generally mean an underground sewage channel, but a water way cut to drain the fen lands. These drains naturally have a very sluggish current and the Bargate drain in question is little better than an open sewer. Out of 11 cases of typhoid fever which occurred in the district during the year 1900 seven occurred in Skirbeck, all of which were in houses along the course of Bargate drain or in its immediate vicinity. The isolation hospital is also severely condemned, and with good reason. The building is an old farm-house; there are no lavatories, all excreta having to be carried through the house, and the drainage, such as it is, is into cesspools in the garden. A new building is, therefore, recommended. It is quite obvious from this report that a great part of the Boston rural district has sanitary arrangements of a most defective character. Dr. Tuxford has pointed this out; therefore he was, if not actually dismissed, at all events not allowed to be re-elected without a contest. The election was held on March 30th and Dr. Tuxford was re-elected. We are eminently glad to see that the matter has adjusted itself in this way. As Mr. Brown, who seconded the motion for advertising the post, remarked at the meeting on March 16th, "We'll take and have the matter brought before the board and then we shall know who comes, and then we can elect the right party which we believe we have a right to elect" Well, the right party has been elected and we congratulate the board. It would have been a disgraceful thing had Dr. Tuxford been able to say with the masterful Hildebrand, "I have loved righteousness and hated iniquity; therefore I die in exile."

A SOLDIER'S EYES.

Sir Frederick Maurice, the general officer commanding the Woolwich District, has called the attention of the officers, non-commissioned officers, and men serving under him to a form of blindness which, he says in plain terms, is a more prolific source of disaster to soldiers than that blindness which the ophthalmic surgeon can treat and of which the presence can be detected with the result that the person afflicted with it is at once removed from the service. Sir Frederick Maurice refers to want of observation of the common objects of every-day life—a want which affects the efficiency of the soldier in barracks and which may some day bring him and his comrades to disaster in the field, and in his order to the troops under him the general commends to all ranks the practice of observation at all times and seasons. With breezy directness and simplicity he gives instances. Buckets are hanging up all round a room and the non-commissioned officer in charge at the moment when they are required has never observed that they are there, or a military policeman who is asked why he is allowing some irregularity replies with evident candour, "I beg your pardon, sir, I did not see it." The unobservant soldier, Sir Frederick Maurice points out, is not merely useless in the army, but is actually dangerous, and the general trusts to his officers to practise and to inculcate the use of faculties which all possess, but the exercise of which can *only be* made habitual by constant and intentional use. We wish Sir Frederick Maurice well in his efforts. To a great extent the facility of observation, like other forms of independent thought, is destroyed by military discipline in our army. In the barrack-yard a soldier must keep his eyes to the front unless ordered to direct them elsewhere, and the soldier in garrison towns performs most of his exercises in the barrack-yard. As a result, the ease with which soldiers of the mother country could lose themselves was a constant cause of comment and ridicule by colonials during the early part of the present war, while one of the stories published of De Wet tells how that elusive leader one night led his men straight through a British camp which barred his way, answering questions in English, and having no objection raised to his progress except by an officers' mess, the members of which grumbled because their meal was suffering from the dust raised by the fugitive Boers. Such a story, if true, affords a good instance of want of observation, when to observe would have implied an interference by the observer in that which apparently did not concern him. The want of observation, however, is not a peculiarity of soldiers, though military discipline may encourage it rather than otherwise. It is to be encountered in all ranks of society at large. The medical man meets with it frequently in his practice in persons who have failed to notice in those around them, even in those towards whom they bear some measure of affection, symptoms which a little mental alertness, coupled with a little sympathetic interest in the affairs of others, would at once have shown to them. Children often suffer thus owing to the want of observation on the part of their parents. In every-day life, moreover, it is not considered quite "good form" to be actively observant. The person who habitually notices to any considerable extent things which do not strictly concern him is, if detected, considered an inquisitive and impertinent person, while children are corrected if their natural desire to observe becomes obtrusive. Sir Frederick Maurice appeals to his officers to consider themselves always on duty in order to acquire and to teach habits which can only be acquired by those always on duty in respect of them, and Major-General Baden-Powell in his work on scouting teaches the same lesson We have suggested some of the causes, psychological rather than physical, which prevent it from being easily learnt and acted upon, and we commend the study of Sir Frederick Maurice's order to others as well as to those to whom it was issued. The necessity for the constant practice of observation by all who are entering the medical profession, at every stage of their training and career, we need not enlarge upon.

THE TEMPERATURE OF WORKSHOPS.

The Factory and Workshop Act of 1895 orders (Section 32) that in every factory and workshop adequate measures shall be taken for securing and maintaining a reasonable temperature in each room in which any person is employed. A dressmaker was recently summoned under this section and was proved to have kept a number of young women at work in a temperature of 50°, 55°, and 51° F., as shown by the thermometer on three occasions on which the factory inspector called. The room was a large one, with two fireplaces—a *provision* which showed that the original builder had recognised its requirements; but some frugal person had blocked up one of the fireplaces and in the other only an asbestos stove was used. The magistrate was satisfied that the Act had been infringed and no doubt he felt sympathy with young women compelled to do needlework in such a temperature, for the recent weather has brought home the discomforts and dangers of cold to most of us. He, however, thought it only necessary to order that the room should be brought into conformity with the Act within six months, subject to a penalty of £1 a day should his order not be complied with. Why six months should have been allowed we confess ourselves unable to understand. If the order had been that, subject to the penalty named, the room should be properly warmed within 48 hours we have no doubt that means would have been found without inordinate expense to raise the temperature by 10 degrees or failing this that the assistants would have been provided with a proper room elsewhere.

POST-GRADUATE STUDY IN THE METROPOLIS.

IT is satisfactory to hear that the association of nine of the metropolitan schools of medicine for post-graduate teaching is fulfilling a want that has been felt for many years. It is evident from the steady increase in the number of tickets issued that practitioners are finding it worth their while to spend seven guineas on a three months' course, or even 10 guineas on a six months' course, including, as it does, the enormous clinical material of nine of the large London hospitals, utilised to the best advantage for the purpose of instruction by so many leading physicians and surgeons of the metropolis. No doubt it is a great attraction to the scheme that anyone who is taking up a particular subject can follow the practice and the teaching of that subject at each of the nine different hospitals and so compare the methods of well-known authorities. A considerable number of colonial and American practitioners are being attracted by the courses.

THE BRITISH CONGRESS ON TUBERCULOSIS.

THIS congress, which has for its aim the prevention of consumption and other forms of tuberculosis, is to be held in the Queen's Hall, London, from July 22nd to July 26th inclusive, under the patronage of His Majesty the King. The President is not yet appointed, but among those holding office as chairmen of councils or committees are Sir William Broadbent, Professor T. Clifford Allbutt, Sir James Crichton Browne, Sir James Blyth, the Right Hon. the Earl of Derby, and Lord Avebury. The sections are four in number: a State and Municipal Section, of which the President is Sir Herbert Maxwell; a Medical Section, President, Sir R. Douglas Powell; a Pathological and Bacteriological Section, President, Professor G. Sims Woodhead; and a Veterinary Section, President, Sir George Brown. The State and Municipal Section will be divided as follows. In the first division will be considered statistical matters; in Division II. the Notification of Tuberculosis; in Division III. the Influence of Housing and Aggregation (these two divisions will be taken together); in Division IV. the Control of Milk and Meat Supplies; and in Division V. the Provision of Sanatoria. Two distinguished foreigners are expected to take part in this section—namely, M. Henri Monod and Dr. A. J. Martin In the Medical Section a discussion will be opened on July 23rd upon Climatology by Dr. C. Theodore Williams and Dr. I. Burney Yeo. On July 24th there will be a discussion upon the Therapeutics and Diagnostic Value of Tuberculin in Human Tuberculosis, to be opened by Dr. Heron, in conjunction with the Pathological Section. On July 25th a discussion will be opened by Professor Allbutt upon Sanatoria for Consumption. Demonstrations are announced upon cases of Skin Tuberculosis and their Treatment, and of the Use of Roentgen Rays in Diagnosis. The discussion in the Pathological Section will be as follows:—On July 23rd: "The Morphological and Physiological Variations of the Bacillus Tuberculosis and its Relations (*a*) to other 'acid-fast' bacilli, and (*b*) to the ray fungus and other streptothrices." To be opened by Dr. Alfred Moeller, Dirig. Aerzt der Heilstatte, Belzig, bei Berlin, and Dr. William Bulloch, bacteriologist and lecturer on bacteriology and general pathology to the London Hospital. On July 24th: "The Tissue-changes and Constitutional Effects Produced by the Various Constituents of Tuberculin." This will be a joint discussion in common with the Medical Section, to be opened by Professor Koch. On July 25th: "The Varieties of Tuberculosis (Morbid Anatomy and Histology)." To be opened by Professor Dr. C. Benda, Urbankrankenhaus, Berlin; Professor Sheridan Delépine, professor of pathology, Victoria University (Owens College), Manchester; and Professor D. J. Hamilton, professor of pathology, University of Aberdeen. On July 26th: "Mixed Infections in Tuberculosis." Amongst others who are expected to take part in the work in this section are Dr. Roux and Professor Metchnikoff, of the Pasteur Institute, Paris. In addition to the papers on the above subjects the secretaries are prepared to receive papers on other points in the pathology of Tuberculosis, which will come on for discussion after the official subjects have been disposed of. The Veterinary Section will deal with such important matters as the Diagnosis of Tuberculosis in Animals during Life (on July 23rd); Tuberculosis and the Milk-supply (on July 24th); Tuberculosis and the Meat-supply (on July 25th); and (on July 26th) the Legislative and other Measures necessary to Combat Tuberculosis amongst Animals. In addition to the work of the sections described above the following public addresses will be given to the whole congress: on Tuesday afternoon (the 23rd) by Professor Koch of Berlin; on Wednesday afternoon by Professor Brouardel of Paris; and on Thursday afternoon by Professor McFadyean of the Royal Veterinary College. The official languages a the congress are English, French, and German. The honorary secretary-general is Mr. Malcolm A. Morris, 20, Hanover-square, London, W. There will be a museum in connexion with the congress divided into a Pathological and Architectural Section. The honorary secretary for Section I. is Dr. W. Jobson Horne, 27, New Cavendish-street, W., and for the Architectural Section Mr. T. W. Cutler, 5, Queen-square, Bloomsbury, W.C.

BACTERIOLOGY AND THE MERCHANDISE MARKS ACT.

IF, as the progressive study of bacteriology seems to teach, fine bacteria make fine flavours, some difficulty may arise as to the proper description of certain goods. It is now well known, for example, that the flavour and aroma of a Havana cigar are due to the operations of a specific microbe during the fermentation of the leaf. Now if a culture of this pure specific microbe be taken and a German leaf be infected with it a cigar may be obtained which is indistinguishable even by connoisseurs in regard to quality and character from the Havana-grown production. How would such a cigar be properly described? This possibility must be seriously considered, for already a patent has been granted in connexion with the use of pure cultures of bacteria for the purpose of favourably influencing the fermentation of tobacco. Thus pure cultures of bacteria from fine West India tobacco have been prepared and transferred to inferior German tobacco in course of fermentation. The flavour of the German tobacco was so greatly improved that it was no longer recognisable as such even by connoisseurs and experienced smokers of the native leaf. Since a specific microbe is productive of the special flavour of the Havana cigar it would not be strictly correct to describe a continental cigar infected with the self-same microbe as containing an unnatural flavour. The flavour, though artificially induced, would be one quite normal and natural to tobacco. Nevertheless the cigar would not be a Havana cigar, although chemically and even from the connoisseur's point of view it was indistinguishable from it. In the same way a specific character may be induced in cheese by sowing it with a special organism. At one time Roquefort cheese was only produced in the village of Roquefort. Now it is produced on a large scale elsewhere, and the cheese so obtained is indistinguishable from the original Roquefort cheese simply because it is sown with the self-same organism which produces the well-known green growth of mould in that cheese. In actual practice bread is allowed to become covered with a luxuriant growth of mould and is then dried and ground, the resulting powder being strewn between the separate layers of the sliced curd. Cheese prepared in this way, though identical for all practical purposes with Roquefort, would be falsely described as Roquefort, that is, as produced in Roquefort. Gorgonzola, Brie, and Stilton could be encouraged to mature in a similar way, though the curd may have been produced hundreds of miles from the original celebrated districts. Again, the creamy flavour of butter is known to be due to a specific organism which has been employed with success in producing a butter of excellent and uniform flavour when formerly it was difficult to secure this attractive quality always. It is clear that as our knowledge of the secrets of nature such as we have described increases, the names of places made famous by the production of a specially excellent article will cease to have a specific meaning for that article. When the microbes of Havana, of Gorgonzola, and of Devonshire (or other celebrated butter-producing districts) come to be successfully cultivated on the large scale the rest is only a matter of infection in order that an article formerly exclusively associated with the names of these places may be produced identical with the native production. It is possible that distinctive flavours are associated with certain centres of production because at these centres the specific organism producing these flavours finds there a congenial environment. Once, therefore, this organism is discovered a monopoly of manufacture and fame would be seriously threatened.

THE EPIDEMIC OF PLAGUE AT ALEXANDRIA IN 1899.[1]

DR. VALASSOPOULO, the head physician of the Greek Hospital at Alexandria, has written a most interesting account of the plague epidemic which prevailed in Alexandria in 1899, commencing at the end of April and reaching its decline towards the end of July. The first case which Dr. Valassopoulo saw was admitted under his care in the Greek Hospital on May 2nd. Although the symptoms were characteristic of plague yet the bacteriological results were not quite decisive. Fifteen days later, however, a second case was admitted showing similar symptoms in which the bacteriological tests were quite conclusive, and Alexandria was therefore officially declared to be plague-infected on May 20th, 1899. It should be mentioned, however, that Dr. Valassopoulo recalls having attended a case at the beginning of April in which there was inguinal bubo with pyrexia. This, in the light of the two other cases, is now looked upon as having been plague. Of these three patients two were grocers' assistants and the third lived in a room attached to a bakery. Dr. Valassopoulo does not arrive at any definite conclusion as to how the disease was imported, but he has no hesitation in affirming that it was spread by rats, and he mentions that in one grocery-store there were found within a few days 200 dead rats and a dead cat. Dr. Valassopoulo divides the cases under his care into two classes only—namely, plague accompanied by external buboes and plague without external buboes. The first form he calls "bubonic plague" and the second "visceral plague." In all he treated 24 cases of undoubted plague, 22 of which belonged to the bubonic form and two to the visceral form. Of the 24 cases 16 patients recovered and eight died. Of these eight deaths seven were cases of bubonic plague and one of visceral (pneumonic) plague. With regard to the methods by which infection is spread Dr. Valassopoulo wisely keeps an open mind. As out-of-the-way instances of infection he cites the case of a young girl who suffered just previously to her menstruation with pruritus vulvæ and apparently was infected through the labia minora which were made raw by scratching; of a man who was probably infected by the pharynx and had enlarged supra-clavicular glands; and of a small boy with an axillary bubo who had a crack in his hand at the junction of the left thumb with the palm. Treatment resolved itself into the general treatment of infectious fevers. Buboes were incised when suppuration appeared and in the case of deep fluctuation being felt in the iliac fossa this collection of pus was let out under the strictest antisepsis. Eleven cases were treated with a curative serum obtained from the Pasteur Institute, of which four patients died and seven recovered. With regard to preventive inoculation as advised by Mr. Haffkine, Dr. Valassopoulo was unable to try it on account of the hostility of the populace, but he considers that it is of use in prophylaxis. The methods of prophylaxis upon which Dr. Valassopoulo relied were the usual ones of isolation both of patients and "contacts," with disinfection of houses, the cleansing of insanitary areas, and the destruction of rats. We have but mentioned the salient points of this report, but we congratulate Dr Valassopoulo upon having written a very clear and practical account of the epidemic.

THE OUT-PATIENT TREATMENT OF INCIPIENT MENTAL DISORDERS.

THE committee of the Dorset County Asylum, at the suggestion of Dr. P. W. Macdonald, the medical superintendent of the County Asylum, Dorchester, have approved of the establishment of an out-patient department at the asylum "to afford an opportunity of consultation, free of charge, to those suffering from mental diseases and kindred affections, especially in their incipient stage." This is a wise provision, tending to the saving of patients from threatened mental breakdown. A department of this kind has been in existence at the West Riding Asylum, Wakefield, for nearly 10 years. In London Dr. Henry Rayner has long had an out-patient clinic for mental disorders at St. Thomas's Hospital. Both of these institutions have, we believe, achieved a considerable measure of success in this special line of medical work. The London County Council have had this important matter under consideration and it is hoped that some practical good may come of it. The adequate treatment of incipient and unconfirmed cases of insanity affords one of the few means at our disposal for dealing with the problem of the increase of insanity. The general practitioner and the family physician see such cases as a matter of course before they come within the survey of the alienist and the establishment of mental clinics for out-patients both at our asylums and hospitals generally would be a great saving of time. The special treatment of the patient would commence much earlier. But provision will have to be made so that this form of medical charity may not be abused. The Dorset County Asylum Committee state that no one is to be deemed eligible for consultation and treatment at their institution except persons of the poorer class who reside in the county of Dorset and whose symptoms are, in the opinion of the medical superintendent, of such a nature as to require advice and treatment of the special character available at the asylum. Persons desirous of availing themselves of such conditions must procure a recommendation on a prescribed form from a medical practitioner, or from a justice of the peace for the county.

[1] La Peste d'Alexandrie en 1899, au Point de Vue Clinique, Épidémiologique, &c. Par le Dr. A. Valassopoulo, médecin-en-chef de l'Hôpital Grec d'Alexandrie Paris: A. Maloine, 1901.

or from a member of the county council, and must attend on a specified day at the out-patient department of the asylum. In Germany out-patient clinics for mental cases are in existence in connexion with nearly every asylum and university and in the United States progress is being made on the same lines, and if we desire to be free from the reproach that we are slow to advance in the field of psychological medicine the establishment of such out-patient departments in our country must become more general.

THE MIDDLESEX HOSPITAL LODGE OF FREEMASONS.

A MASONIC Lodge has been founded in connexion with Middlesex Hospital, and its consecration will take place on *Tuesday, May 7th.* The officers named in the warrant are T. J. A. Burns, M.R.C.S. Eng., as Worshipful Master; W. Duncan, M.D. Brux., F.R.C.S. Eng., as Senior Warden; and F. J. Wethered, M.D., F.R.C.P. Lond., as Junior Warden. Mr. Henry Morris, F.R.C.S. Eng., will, we understand, be the Treasurer. This is the third Masonic Lodge that has within recent years been founded in connexion with the great London hospitals, the other two being the Rahere Lodge associated with St. Bartholomew's and the Sancta Maria Lodge with St. Mary's. The Middlesex Hospital Lodge starts under good auspices and will, we trust, prove as successful as have the Rahere and the Sancta Maria Lodges. Particulars concerning the new lodge can be obtained by Freemasons connected with the hospital from the secretary, Mr. F. Clare Melhado, Middlesex Hospital, W.

THE CENSUS AND THE MEDICAL PROFESSION.

SEVERAL correspondents have written to us pointing out in somewhat expostulatory terms that although the Registrar-General gives explicit directions to the clergy and to the members of the legal profession yet he ignores the existence of the medical profession. We think, however, that a little consideration of the subject will show our correspondents that the Registrar-General has reason on his side. The legal profession is subdivided into barristers and solicitors, while articled clerks and other clerks have a recognised place in it without forming an integral part of it. In the case of the clergy again there are bishops, priests, and deacons of the English Church, of the Roman Church, and of the Orthodox Eastern Church, though we fancy that in the last case there is no bishop resident in these islands, and there are many sub-classes of nonconformity. If a man describes himself on the census paper simply as "priest" or "deacon" he gives rise to confusion. But the medical profession is one. A man passes certain examinations which give him the right to be enrolled upon the Medical Register. Being there he is entitled to describe himself as a medical practitioner and no one else should have such a right. Our correspondents would join us in warmly resenting the inclusion of quacks.

SALINE INJECTIONS IN MYALGIA AND SCIATICA.

AT the meeting of the Société Médicale des Hôpitaux of Paris on March 8th, M. Bernard reported that he had obtained very encouraging results from saline injections in lumbago, pleurodynia, and sciatica. In one case a man had suffered from sciatica for six years. The disability was absolute, the pains were very acute, and the insomnia was constant. The first night after the injection the patient slept well, the improvement continued, and at the end of a fortnight he was free from all pain and could walk easily. Three months after the cessation of treatment the improvement was maintained. In more than 20 cases of sciatica, some of which were very severe and attended by almost complete disability, the greater number of the patients were much improved in two or three days, and almost completely cured in a period varying from eight to 20 days. Equally satisfactory results were obtained in pleurodynia and myalgia. In a case of muscular rheumatism the patient, who had been treated without benefit for six months, lost both pain and disability after he had received two injections. The procedure consists in injecting five cubic centimetres of normal saline solution at the most painful points. In some cases three or four injections were given on the same day.

THE STOURPORT MEDICAL ASSOCIATION AND THE KIDDERMINSTER MEDICAL SOCIETY.

DR. R. SAUNDBY has received the following letter from the honorary secretary of the Kidderminster Medical Society with reference to that body and the Stourport Medical Association:—

"DEAR SIR,—I have to inform you that the Stourport Medical Association have amended their rules in such a way as to (1) prohibit canvassing; (2) confine their membership solely to the wage-earning classes; and (3) ensure that there shall be no funding of moneys to a greater amount than £100. The disabilities imposed by the Kidderminster Medical Society upon their medical officer have now been removed. I should be obliged if you would kindly notify the secretary of the Birmingham Branch of the British Medical Association of this fact.

"I am, yours very truly,
"O. O. PENRHYS EVANS,
"Honorary secretary Kidderminster Medical Society."

This would appear to announce the termination of a struggle in which the Birmingham and Midland Counties Branch of the British Medical Association gave support to the medical profession in Kidderminster and Stourport.

H.M. the King of Italy has been graciously pleased to promote Sir William Mac Cormac to the degree of Grand Officer of the Order of the Crown of that country. This is the second grade of the Order, the first being the Grand Cordon. It derives its name from the Iron Crown of Lombardy. Sir William MacCormac has been for many years consulting surgeon to the Italian Hospital in London.

SEVERAL daily papers have announced that Sir Dyce Duckworth has resigned his office of physician to St. Bartholomew's Hospital. This is an error and one that might seriously inconvenience its victim. Sir Dyce Duckworth has resigned his lectureship on medicine after 12 years' service, but he remains physician to the hospital.

THE King has approved of Deputy Surgeon-General Charles Benjamin Mosse, C.B., C.M.G., A.M.D. (retired), (Superintending Medical Officer), and Dr. John Pringle, C.M.G. (Member of the Privy Council), being nominated Members of the Legislative Council of the Island of Jamaica.

WE have received from the laboratory of the Scottish Asylums, 7, Hill-square, Edinburgh, two reports for the year 1900—namely, the report of the General Board and the fourth annual report by the pathologist, Dr. W. Ford Robertson. An extended notice will appear in due course.

THE inaugural meeting of the Society for the Study of Psychology by Experimental Methods will be held, by the kind permission of Dr. G. H. Savage, at 3, Henrietta-street, Cavendish-square, London, W., on Tuesday, April 16th, at 5 P.M.

BUBONIC plague at the Cape is, according to Dr. Gregory, principal Government medical officer, becoming more and more virulent. On April 1st there were two fresh cases among Europeans and four among the coloured population.

AT a meeting of the Comitia of the Royal College of Physicians of London held on Monday last Sir William Selby Church, Bart, M.D, was re-elected President by the practically unanimous vote of the Fellows

HISTORY OF RENAL SURGERY.

BY DAVID NEWMAN, M D, F F.P.S GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

IV[1]

NEPHRORRHAPHY.

THE next operation called into requisition was first performed by *Dowell of New Orleans who fixed the kidney* by a tape suture in 1874,[2] but it was first called "nephrorrhaphy" by Hahn of Berlin, and afterwards named by the French writers "nephropexy" In 1880[3] I suggested stitching the kidney to the abdominal wall in a case sent to me by Dr J. M. Yair of Kilcreggan, but it was not carried into execution till three years later.

The credit of introducing the operation to the profession *belongs to Dr* E Hahn who performed his first operation in April, 1881. He exposed the capsule of the kidney by an incision in the loin between the twelfth rib and the crest of the ilium, along the edge of the sacro lumbalis muscle The fatty capsule was opened along the outer border of the kidney, the perinephric fat was drawn into the wound, sutured to the fascia by half a dozen catgut sutures, and the wound was plugged with gauze The first six nephrorrhaphies were performed by Hahn; then in Germany by Delhaes, Kuster, Esmarch, and Luenstein; in Italy by Bassini, in America by Weir, each one operation; and in this country the writer performed two nephrorrhaphies before the end of 1883 All these cases were successful In the five years 1881 to 1885 35 nephrorrhaphies were performed with one death, and in the following five years (from 1886 to 1890) 139 with four deaths, which, considering the condition of many of the cases operated upon, is a very [illegible] in the place of [illegible] a distinct adva[illegible] the treatment [illegible] patients recov[illegible] high to prevent extirpation being resorted to except in extreme cases where nephrorrhaphy had failed to give relief. The advantages are very evident The mortality is in nephrorrhaphy one tenth of what it is in nephrectomy. No renal tissue is removed; the operation can be performed on both sides and the peritoneum is not opened. As performed by Hahn the operation did not always permanently fix the kidney, but *as it is now done* little difficulty should be found in anchoring the organ in the lumbar region.

INCISION OF THE KIDNEY.

Incision of the kidney and division of the fibrous capsule for the relief of pain was first suggested by Tiffany of Baltimore in 1885 and demonstrated by him to be a successful operation in cases of so-called "nephralgia" In this country Mr. Reginald Harrison[4] and the present writer[5] have employed incision of the kidney to relieve the pain and other symptoms arising from increased vascular tension of the renal tissue Although the value of the operation has been verified by many others, the importance of the treatment has not been sufficiently recognised as a means of relieving severe renal suffering and preventing suppression of urine

RESECTION OF THE KIDNEY.

Resection of a kidney or partial excision was for a long time thought to be an extremely dangerous procedure, and even still few cases have been ventured upon, partly from fear of hæmorrhage during the operation but also from want of confidence that the wound in the renal parenchyma would heal satisfactorily Tuffier[6] showed by his experiments upon animals that during the operation the bleeding can be easily controlled and that wounds of the kidney heal rapidly Considering the very vascular condition of the organ this is to be expected The first surgeon to perform a partial excision of the kidney was Czerny[7] who operated for an angio-sarcoma on the convex aspect of a kidney in November, 1887 The wound was partly sutured and partly tamponated Two years later Kummell, and succeeding him Bardenheuer, Tuffier, and Bloch, performed partial resection of the kidney, and some of them more than once Up to the present close upon two dozen such operations have been published and on the whole the results are very encouraging, although in a few instances the partial excision is required to be followed by a complete nephrectomy

The conditions of the kidney most suitable for partial excision are maladies such as perinephric tumours and growths in *the cortex of the kidney which are strictly* localised or involve only a small portion of the organ Out of 21 cases of perinephric tumours[8] in 14 the kidney was removed along with the growth, while in seven the tumour was simply excised from the fibrous capsule. Again, in benign tumours, when they can be diagnosed at the operation, a partial excision is indicated, and for certain cystic formations the same remark applies The operation has also been resorted to in suppurative disease with or without calculus, in urinary fistula, and in tuberculous disease, but for these conditions it is not suitable Injuries of the kidney have on many occasions been treated by this method and with a good result Bardenheuer in Germany, E Owen and Keetley in this country, and Dr Nash in New South Wales have advocated its adoption Dr Arthur Barth gives a very full account of the process of healing in wounds of the kidney in von Langenbeck's *Archiv*[9]

OPERATIONS ON THE URETERS.

Operations upon the ureters may be looked upon as a development of the last few years, indeed, previously to 1887 there were only two ways of treating a fistula arising from division of the ureter or an obstruction of the duct—to let it alone or to perform a nephrectomy. But it is of interest to note that Turner[10] gives the following quotation by Caspar Bauhine:—

[illegible] after ensuing

Velpeau[11] mentions a case of a small calculus impacted in the right ureter three inches below the kidney where the posterior wall of the ureter was perforated by an ulcer, suppuration was set up in the adipose tissue behind the peritoneum, and an abscess extended from the level of the kidney to the floor of the pelvis Velpeau maintained that the calculus could have been removed by an incision in the *flank*

ureter. He pointed out the intimate relation of the ureter with the peritoneum, and that it is the peritoneum which maintains the ureter in contact with the psoas magnus. This led him to explain the rationale of enforced walking exercise upon a calculus impacted in the ureter; the contraction of the fibres of the psoas he thought communicated to the ureter a sort of peristaltic action which made the stone descend towards the bladder.

He gave the explanation based on his anatomical knowledge and upon a post-mortem examination of a case in which he found a moveable right kidney opposite the third and fourth lumbar vertebræ, of the occurrence of hydronephrosis in association with moveable kidney. This, be it observed, was 42 years before the same explanation was credited to Landau, Terrier, and Baudoin respectively. He attributed it to kinking of the ureter, which, fixed by the peritoneum, cannot follow the kidney in its displacements, and thus causes it to form a curve with the convexity upwards, all the more pronounced as the kidney gets lower and lower. The result of this curvature, he thought, was to obstruct the urine, or even to render its flow impossible. Finally, he described the operations of ureterotomy and lumbar ureterostomy precisely as they are now performed. Gigon thought that the obstruction to the free flow of urine due to the kinking of the ureter was a predisposing cause of stone in moveable kidneys.

OPERATIONS ON THE URETERS FOR STONES.

Calculi which have become impacted in the ureter may now be removed, but the operative procedure depends upon the position occupied by the stone. 1. When the stone is sufficiently low down to be detected by digital examination in the vagina or rectum the stone may be removed through the bladder, the rectum, or the vagina. 2. When the stone is too high up to be felt by the finger, but occupies the middle third of the ureter, it must be removed by an incision through the abdominal parietes but without opening the peritoneum. 3. When the stone is in the upper third of the ureter the kidney should be incised and an endeavour made to extract the calculus through the renal pelvis.

Emmit, Berg, Richmond, Czerny, Sänger, and the present writer have removed stones from the lower end of the ureter in the female by dilating the urethra and the ureter. Ceci removed a calculus through the rectum and Fenwick employed a perineal incision. Removal through the vagina has been practised by Cabot, Emmit, Cotterall, Fenwick, and Regney, and the writer has removed a stone from the ureter in two cases by suprapubic cystotomy. In 1887, through an incision in the lumbar region, Godlee performed a retro-peritoneal ureterotomy, and the same method was adopted by Kirkham and Torrey in 1889. Since then the method has been followed by Cabot, by Ralfe, by Finger, and by many others.

In operations through a wound in the lumbar region the ureter should be carefully searched, and if a stone be found it may in some instances be readily pushed up into the pelvis and removed by an incision through the convex border of the kidney. An incision through the substance of the kidney heals more readily than one through the wall of the pelvis. Supposing, however, that a stone is not found in the first examination with the kidney in its normal position the attachments of the organ must be freed and the organ brought out through the wound sufficiently to permit the surgeon making a thorough examination. When the hand fails to discover the presence of a stone an incision should be made through the kidney on its outer aspect, and through the wound a digital exploration of the pelvis and calices should be made, and if a stone is found it may be removed. After the stone is extracted a ureteral catheter or sound should be passed down the ureter into the bladder so as to ensure that the passage is clear. It is not uncommon to find calculi both in the pelvis and ureter. If a stone is discovered in the lumen of the duct an attempt should be made to press it up towards the kidney, and generally this is easily accomplished as the ureter is dilated above the point of impaction of the stone, but if it is firmly fixed an incision should be made through the wall to the ureter, and after the calculus has been extracted the incision may be closed by sutures.

Intra-peritoneal ureterotomy has been performed in two cases—one by Cullingworth and the other by Lane. The patient in the former case died and in the latter recovered, but on account of the danger of contaminating the peritoneal cavity the operation has not been recommended.

OPERATIONS FOR THE RELIEF OF KINKING, STRICTURE, AND VALVULAR OBSTRUCTION.

Simon[12] was the first surgeon who indicated the treatment of stricture and valvular obstruction by operation, and in 1890 Trendelenburg[13] attempted to relieve a large hydronephrosis by shortening the ureter and transplanting it from the side to the bottom of the sac. The result of the operation was uncertain and the patient died from ileus. The following year Kuster[14] attempted a very similar operation, but finding a stricture in the ureter abandoned transplantation for resection. The first successful case of ureterotomy for valvular obstruction of the ureter was performed by Fenger of Chicago in 1892[15] for hydronephrosis in a moveable kidney. The valve was divided and the ends were united by suture while the moveable kidney was fixed. He performed a second operation in the same year for cicatricial stenosis. In 1893 Mynter[16] also had a successful operation, and Morris, in his Hunterian Lectures at p. 20, describes a case of his own.

In many cases of moveable kidney the displacement of the organ leads to kinking of the ureter and transitory hydronephrosis, a condition which may be remedied by fixing the kidney high up so as to stretch and straighten the elongated duct. I called attention to this many years ago,[17] and since then I have operated successfully upon nine cases of transitory hydronephrosis in moveable kidney by the method just indicated. It is both safer and more successful than resection of the ureter in the cases referred to.

When the ureter has been divided by injury, or when a section is made for the purpose of remedying a diseased condition, the two segments may be joined or the upper portion of the duct may be implanted into the bladder, the vagina, the large and small intestine, or on the skin in the loin. These operations are being resorted to, not only in cases of stricture and wounds of the ureters for ulceration or sloughing around a calculus, but also in tumours of the bladder requiring resection of the organ and in ectopion vesicæ. When there is little loss of tissue so that the length of the duct permits of it the two segments should be reunited. This has been done in four different ways:—1. The transverse end-to-end method was first performed by Schopf[18] in 1886. Transverse wounds of the ureter tend to gape and there is considerable danger of stenosis at the point of union, but the advantage of this method is that there is no loss to the length of the duct. This operation has been performed 12 times.[19] 2. The oblique end-to-end method devised by Bovee has only been done once; the patient is still (1900) free from any symptoms referable to the urinary passages, four years after the operation. 3. The end-in-end operation devised by Poggi[20] from experiments upon dogs has been very successful. In this method the upper segment of the duct is invaginated into the lower segment, and if necessary the latter is split for a short distance. It has been performed nine times with one death. 4. The end-in-side implantation has been also employed to unite the cut ends of the ureters. The method was introduced by van Hook in 1893 and is as follows. The lower segment is closed at its upper end by a ligature, and a quarter of an inch below it a longitudinal incision is made twice as long as the diameter of the duct. In the upper segment a longitudinal incision is made beginning at the free end and extending upwards for a quarter of an inch. On the side of the upper segment, immediately opposite the slit, the two free ends of a suture are passed from within outwards, about an eighth of an inch apart and an eighth of an inch from the extremity of the ureter. The free ends are then carried through the slit in the lower segment and passed from within outwards half an inch lower down. When the suture is tied the open end of the upper segment is drawn into the slit in the lower segment. The walls may then be secured by fine sutures and enveloped in peritoneum. This method has been employed by Kelly, Emmit, Schanta, Doherty, and Reynier in operating upon women. It is not easy to decide which method is the best. The advantage of the transverse end-to-end method is that in it none of the length of the ureter is sacrificed, whereas in the oblique end-in-end operation and in the lateral anastomoses of Hook the loss must be at least half an inch and may be more. Of course, if the length of the ureter appears too short the kidney may be brought down to compensate for the loss or by separating the attachments of the duct for a few inches above and below the point of section.

When the loss of substance has been too great to permit of uretero-ureteral anastomoses grafting the end of the ureter into other parts has been resorted to. The one most frequently employed is uretero-cystostomy or implantation of the ureter into the bladder. Vesical grafting has been carried out in four different ways: (1) grafting the ureter to the bladder through the vagina; (2) grafting the ureter to the bladder by an extra-peritoneal route, an incision being made through the abdominal wall; (3) by an intra-peritoneal operation; or (4) by dividing the vesico-vaginal septum and grafting the ureter to the bladder direct. The first operation, according to Bovee, was performed by Tauffer in 1877. The next operation was done by Novaro in 1893, and since that time 60 uretero-cystotomies have been performed.

[20] Riforma Medica, 1887-88, p. 39.

Grafting of the ureter to the vagina has been very seldom performed and is not a satisfactory operation. It has been done by Pawlik, Chavasse, and Kossinsky. The ureter has also been implanted on the urethra five times.

Implantation of the ureter into the bowel has also been employed, but the strong objection to this method is that septic infection is very liable to extend upwards to the kidney. Experimental implanation into the rectum, the colon, and the small intestine has been studied by Rosenberg, Novaro, Morestin, Tuffier, Gluck and Zeller, van Hook, and many others, but the operations performed upon animals contrast unfavourably with those undertaken on man. According to Bovee, bowel implantation has been done 65 times on man with a mortality of 30 per cent, and a little less than a half of these were from subsequent ascending infection.

Many different methods have been employed: (1) Simon in 1851 did the first operation of this kind in a case of ectopion vesicæ by placing a loop of thread so as to make it ulcerate through adjoining parts of ureter and rectum and producing a fistula between them; (2) implantation of both ureters with pieces of the bladder attached, as by Pozza; or (3) grafting the ureter with a flap of vesical mucous membrane only. The majority of these operations have been employed *on account of gynæcological operations* in which the ureters have been accidentally wounded or divided in operation for uterine or ovarian disease, and especially in vaginal hysterectomies. They have also been used in cases where the bladder had to be resected for malignant tumours.

Implantation of the ureter on the skin has been resorted to in a considerable number of cases, Le Dentu being the first to employ it, but it seems to be justified only as a temporary measure or to save the patient from immediate death by anuria. Skin-grafting should only be resorted to when, from loss of substance, no other method is possible or to tide over a critical period, after which another implantation may be made or nephrectomy *performed. As a rule*, if implantation cannot be made into some part of the urinary tract, it should be made into the bowel, or if the kidney on the opposite side is healthy nephrectomy should be performed.

IRRIGATION OF THE KIDNEY.

Irrigation of the kidney *viâ* the ureters has been employed in a considerable number of cases and is said to be attended with good results. When it can be tolerated by the patient temporary good may be done, but the difficulties in carrying it out are so great and so irksome to the patient that incision of the kidney is to be preferred in most cases as a means of *giving an exit to discharges.*

Simon was the first to attempt the production of a systematic treatise on the surgery of the kidneys, but only the first two parts appeared. The third part, which was reserved for the consideration of cystic disease, tuberculosis, and moveable kidney, he did not live to complete. Subsequently to the appearance of his work, but 10 years later, the following books came out in succession: in 1885 Morris,[21] in 1886 Bruce Clark,[22] in 1888 Newman,[23] in 1889 Tuffier,[24] in 1890 Knowsley Thornton,[25] and in 1896 the first volume of Küster.[26]

The success of the surgeon in his treatment of renal disease largely depends upon his ability to detect lesions in their early stages. Consideration cannot be given to the development of the more exact diagnostic methods which have come into use in recent times, but it is quite certain that the means now at his disposal enable the surgeon to intervene at the onset of the disease and under the most favourable circumstances. When the operator is able to satisfy himself as to the nature and the extent of the disease the work he has to do is already clearly marked out. What we most require now in many cases is clearer insight in forming an early diagnosis It is not how, but when, should we operate, also when should we withhold our hand so that we may be sure "to do good or to do no harm."

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 965)

VII.

WE may pass over Lord Methuen's advance (pages 19 and 20), with the remark that while the Commissioners consider that the medical arrangements were well devised and carried out there was some delay in establishing stationary hospitals at Orange river and Modder river. Lord Methuen's advance had a great advantage over that of Lord Roberts, in that the latter, having no line of railway communication with the base, had of necessity to use field hospitals as fixed hospitals for considerable periods. Kimberley was relieved on Feb. 15th, 1900. General Cronje's army was surrounded at Paardeberg from Feb. 16th to the 27th, when it surrendered. On March 6th the advance on Bloemfontein commenced, and after considerable fighting *en route* it was reached on the 13th. The facts in connexion with this part of the campaign from a military point of view are taken chiefly from the evidence of Lord Roberts, Lord Kitchener, Surgeon-General Wilson, and Major Bedford. We may note the following:—To ensure the mobility of the Kimberley relief column the transport was cut down to a minimum, the ordinary baggage of the column was left behind at Modder river, and the men had to advance with no change of clothing. Surgeon-General Wilson having declared that he could not carry out the medical arrangements for the advance with less than the minimum of transport allowed by the army regulations, had to yield to military necessity and to accept the decision of the Commander-in-Chief as he was bound to do. "Nothing but military necessities would have justified the reduction. It is not for us to question the decision of the military authorities, but we may say that we are convinced that the necessities justified the step taken by them and that the suffering thereby occasioned was part of the price that had to be paid for success in the campaign" (pages 21 and 22 of Report).

We need here only give a brief notice of a few important points. It was thought that when Kimberley was relieved the column, with its hospital service which was for military and transport reasons cut down to the utmost, would be again in touch with the railway for the transport of the sick and wounded to the stationary and base hospitals; but the unexpected movement of Cronje's force altogether changed the nature and course of the campaign. Up to Paardeberg the only way of dealing with the sick and wounded was to send them back to Modder river and Kimberley. The stationary hospital at the former place and the hospital at Kimberley acted as two base hospitals during the first part of the advance on Bloemfontein. Had there been a general hospital at Orange river it is admitted that the strain would have been very materially relieved. The reasons given for failing to plant a general hospital at this point are given (page 22 of the report). The treatment of the sick and wounded at Paardeberg was carried on under a great strain. The enemy were threatening the position, the sickness was increasing, there was no proper accommodation, the evacuation of the field hospitals had to be rapidly effected for an impending advance, and the sick were sent to Kimberley or the Modder river. The British medical authorities had, moreover, to take over all the Boer sick and wounded.

The British army operating in South Africa was almost entirely composed of a material most susceptible to enteric fever. Roughly speaking, the age from 18 to 30 years is the time of life which may be said to be the enteric fever age in all countries. The South African army was composed of men of those ages and they were all, moreover, recent arrivals in that country. Now, it has been thoroughly established statistically in India that it is during the first and second years of Indian service, and more especially during the first year, that this susceptibility is so marked. Out of the total number of British troops of all ages who died from enteric fever in India in 1898, for example, 74 per cent. were between 20 and 25 years of age; and comparing equal percentages of soldiers during their first, second, and third years of Indian service their liabilities to contract enteric fever were respectively 43, 18, and 12. The greater the supply of susceptible material the greater the prevalence of enteric fever. We may conclude, therefore, that it was something more than a mere coincidence that during 1899 there was a great fall in the amount of this fever in the Indian army. The enteric fever admission-rate in India during 1899 was 20·6 and the death-rate 5·14 per 1000: whereas in the preceding year (1898) the rates were 36·9 and 10·17 respectively. The mortality-rate from enteric fever in the Indian army for 1899 was lower than it had been for nine years previously. There may have been, and probably were, other factors at work, but owing to the war in South Africa soldiers of longer service were being retained in India and fewer reinforcements of susceptible material from home were sent out there. Whether it be acclimatisation, or survival of the fittest, or some other cause, be it what it may, that confers the immunity, the fact remains that a short-service army newly arrived in a tropical or sub-tropical climate is a peculiarly vulnerable one in respect of typhoid fever. Like all stories worth the telling the moral lies on the surface, and it is easy of application to the case of the army in South Africa. When a spark of the disease-cause lighted upon such inflammable material, environed by the conditions in which that army was, a sudden and general conflagration of enteric fever was only to be expected. Our knowledge, too, has increased with regard to the etiology and pathology of the disease, how many may be the channels of infection, and how long such infection may last. We do not, as we have said, attach much importance to any comparative statistical returns of case-mortality unless assured that the bases of comparison were the same or very similar. The diagnosis of enteric fever in other armies—that of the Germans, for instance—is much more inclusive than ours. It is clear that the inclusion of cases of continued fever among those of enteric fever would tend proportionately to reduce the percentage ratio of case-mortality of the latter, and this is the probable explanation of the lower rates of mortality usually recorded in the epidemic outbreaks of typhoid fever in the German army before Paris and elsewhere during the Franco-German war of 1870.

But to return to the report of the Commission. The march from Osfontein, whither the troops had been removed from the fouled ground at Paardeberg, to Bloemfontein began on March 6th, 1900. There was fighting on the way at Driefontein with the result of an addition of 361 to the list of wounded. The whole difficulty on that occasion was one of transport. "Viewed as a whole, and considering the difficulties and nature of the advance, the cutting down of the transport and ambulances, and the deficient staff of the Royal Army Medical Corps, we think that the medical authorities did their best to deal with the situation." The force reached Bloemfontein on March 13th. In the beginning of April Surgeon-General Wilson telegraphed to England for more general hospitals and more civil surgeons, and on arriving at Bloemfontein on April 23rd, seeing the position of affairs there then, he sought for and obtained more doctors and nurses in South Africa itself. But these steps came rather late. The deficiencies of the staff at Bloemfontein and the lack of sufficient nurses were not realised as soon as they might have been. Although it was right under the circumstances not to convert the hotels into hospitals, yet one or more of the hotels might have been employed to afford accommodation for nurses. The report also points out that commandeering might have been carried out on a far larger scale to secure beds and other hospital furniture and clothing.

The field hospitals were not, we are told, overcrowded on arrival, but sickness on a great and alarming scale soon occurred. It was not so much the amount, as the suddenness with which such large numbers were almost simultaneously attacked; that caused the excessive strain. The conditions were those which we have already set forth. Field hospitals, never intended for other than very temporary occupation, soon became overcrowded. There was not only a deficiency of buildings that could be utilised for hospitals at Bloemfontein, but a deficiency of medical staff and equipment for those that were utilised as such. These buildings and the field hospitals formed the only accommodation for the sick and wounded until the arrival of No. 8, No. 9, and No. 10 Hospitals (page 26 of report). All the buildings (except the Raadzaal) used as hospitals in Bloemfontein were taken over by No. 10 General Hospital. The Raadzaal was taken over by No. 5 Stationary Hospital, and to this hospital accommodation the Portland Hospital, the Irish Hospital, and the Langman Hospital contributed in the first part of April an additional 300 beds between them. It was later that the suffering from overcrowding and want of equipment occurred, but the field hospitals were rapidly becoming more and more congested. On the advance of the force from Bloemfontein to Kroonstad in the beginning of May the field hospitals, in order to accompany the troops, had to be cleared of their patients, and large numbers of sick and wounded had to be sent back from the advancing force. All who were in excess of the accommodation and could not be taken into the buildings and private hospitals poured into the imperfectly equipped and under-staffed hospitals No. 8 and No. 9 where there were no means of stopping any influx in excess of the accommodation. The result of all this was for a time a deplorable amount of misery and suffering at Bloemfontein. In June the condition of things became much better owing to the fact that transport by rail had improved and access to the hospitals on the lines of communication and at the base had been again opened up. The strength of a chain is only that of its weakest link and the links of the medical administrative chain were not apparently of the strongest at Bloemfontein. The Commissioners, while freely admitting the sudden and for a time overwhelming nature of the epidemic outbreak, leave it to be plainly inferred that the management and arrangements connected with No. 8 and No. 9 Hospitals left very much to be desired.

The condition of No. 8 General Hospital was unsatisfactory from its start and it did not begin to take in patients at Bloemfontein until about April 23rd, 1900. There is no doubt that, in addition to overcrowding, the state of this hospital was very unsatisfactory, in point of staff, equipment, dieting, and several other respects. What with the sudden influx of numbers and one thing and another its condition grew worse and worse, as will be seen by reference to pages 32 and 33 of the report. The Commissioners, after making due allowance for the great difficulties that had to be encountered, are not at all satisfied that the best had been done in the way of energy and of administrative and organising power on the part of its principal officers. To add to the difficulties, at a time when the services of capable, clear-headed, and tactful officers should have been directing the management of affairs and all should have been animated with one and the same object and should have been striving together to attain it, there were "internal dissensions and friction" between the civil surgeons in the hospital and the officers of the Royal Army Medical Corps and even between the senior officers of the Royal Army Medical Corps themselves. That was a state of affairs which, as the Commissioners say, "could only result in disorganisation."

As to the conditions of No. 9 Hospital they were very similar to those of No. 8; but it had, upon the whole, an excellent staff, the different members of which worked well together. The overcrowding was even greater in this hospital than in No. 8 owing to the fact of its being near to the railway-station. The hospital, equipped for 520 beds only, opened about April 19th, 1900. In May the influx of patients kept increasing until it had, after May 6th, reached a maximum of 1644. The condition of things, as a whole, was much what it was in No. 8, and as an indication of the strain it may be mentioned that its kitchen, as in No, 8, which was originally prepared for 520 patients only, had for a time to prepare food for an average of over 1200. These grave defects the Commissioners ascribe to the use of field hospitals as stationary hospitals, while in the case of No. 8 and No. 9 Hospitals they were to a large extent due to difficulties of transport. The only course open to the medical authorities was to have taken and to have equipped buildings as hospitals as soon as possible, after the occupation of the town and to have hurried up the general and stationary hospitals with their staff and equipment. But it is not every public or private building that is at all suitable for a hospital—indeed, for sanitary reasons, few are—and a number of small buildings means difficult administration and great waste of *personnel* and *matériel*. Fixed hospitals, it must be remembered, too, are not exempt from capture under the Geneva Convention, and for some time before Bloemfontein was occupied fixed hospitals could not be posted near that town owing to the proximity of the enemy. The facts connected with the arrival of the hospitals (other than field hospitals) in the town are set forth and the Commissioners say, "On the whole we do not think that there is any blame to be attached to the medical authorities in respect of the circumstances and times under which these hospitals were sent up to Bloemfontein" (pages 36 to 38 of the report). The Commissioners then deal from an independent and critical standpoint with the delay in bringing up the staff and in supplying necessary articles and with several other matters affording substantial grounds of complaint Concerning the charges against hospital management at Bloemfontein generally, the following is the summing-up at pages 44 and 45 of the report: "As regards certain general charges, we think it only right to say that a false impression is conveyed of the state of things existing at Bloemfontein by such statements as these, to the effect that in particular hospitals there were thousands of men in deadly disease, or that thousands of men were left unnursed, or that men were dying against convalescents in the tents (though no doubt in a few cases men may have died next convalescents), or other like general statements. The substantial grounds of complaint at Bloemfontein we have sufficiently pointed out above, and there is nothing in them to justify any charge of inhumanity or of gross or wilful neglect or of disregard for the sufferings of the sick and wounded on the part of the medical authorities or others having the duty of looking after them."

We have striven to depict the situation at Bloemfontein as it has impressed itself upon our minds, and, deplorable as it was, what does it really amount to? The causes which brought it about were mainly military (strategical) exigencies, insufficient transport, and a sudden and well-nigh overwhelming outbreak of enteric fever. We are far from saying that there were no mistakes or serious defects, no wasted or misused energy, or that the arrangements for the convenience and comfort of the troops and of the sick and wounded in the way of accommodation, transport, feeding, and so forth, were all that we hope to see them in future campaigns. The evils were serious and should not be minimised, and steps ought to be taken with a view of remedying them.

We need not enter upon any detailed account of the advance to Kroonstad because in many respects it was similar to and subject to much the same conditions as those attending on the advance to Bloemfontein. In one respect they differed, inasmuch as on the very first occupation of Kroonstad commandeering was resorted to and most necessaries were obtained for the hospitals. The Commissioners think, however, that with regard to a few things commandeering was not pushed to the full extent to which it might have been. The troubles at Kroonstad were undoubtedly chiefly due to three causes, say the Commissioners—namely, the insufficiency in number of the field hospitals, the deficiency in point of numbers of the Royal Army Medical Corps staff, and the difficulties of transport (pages 50 and 51)

SUPPLEMENTARY BATHS AT HOTELS.

AN encouraging feature of modern hotels is the attention that is being directed to the provision not only of ordinary baths but of other baths also The comforts of an hotel are undoubtedly enhanced when, for example, the equipment includes special baths, such as Turkish baths, hot or cold sea-water baths, and electric baths, and a source of considerable attraction and value is thereby gained. The English people are slowly but surely realising that treatment by means of baths for the relief of certain ailments such as gout and rheumatism may be just as efficiently conducted at home as abroad.

We have already described in our columns[1] the ferruginous baths recently adopted at Shanklin, which are identical in composition with those of Homburg, Spa, and Schwalbach on the Continent. A similar example of worthy enterprise may be seen in an interesting installation of various baths which has recently been made at the old historic hotel, the Granville at Ramsgate. This hotel, which has been entirely remodelled in accordance with modern requirements, was originally designed by Mr. Welby Pugin, a member of a noted family of architects who one and all contributed largely to some of the excellent specimens of architecture to be found in the old Kentish town. Besides sea-water baths, hot and cold, the new installation comprises a spacious Turkish bath with the usual cooling-room, hot rooms, shampooing-rooms, and a douche-room, and also a plunge sea-water bath. The plunge bath is contained in a room 37 feet long and 17 feet wide, the depth alternating from two and a half to five and a half feet. The accommodation of this plunge-bath is such as to permit swimming exercise and the bath communicates directly with the Turkish baths. In addition a series of baths has been installed which are adapted for so called "ozone" treatment which in reality means a seaweed bath. For this purpose carefully selected seaweed is crushed in order to express its juice as much as possible in warm sea-water until a somewhat slimy liquid is obtained. It may be diluted with hot sea water at will. The efficacy of this bath in gout and rheumatism is, perhaps, due in part to the absorption of the peculiar organic compounds of iodine, in part to the effect of the seaweed as a kind of warm cataplasm, and in part to the action of the sea-minerals The odour of seaweed thus treated is very strong and the vapour of the bath gives a sense of relief in irritable conditions of the respiratory tract. All these baths are situated in an annexe of the hotel, while the hotel itself is fitted throughout with baths provided with a special stop cock which will supply sea water hot, warm, or cold, or fresh water by moving the indicator of the stop-cock opposite to the name on an enamelled plate indicating the supply required. The installation is quite a new departure. The sea water supply is drawn from a selected spot and elevated to a tower where the sand and other suspended matters are allowed to subside At the basement of the building is a modern installation of electrical machinery, and water-heaters. The hotel is thus provided with remarkable facilities for keeping an installation of baths in going order.

It is proposed to add to this already excellent equipment a series of electrical baths and other baths as the need for such may be felt, the addition of other special baths being a simple matter with such facilities at hand. The enterprise is worthy of all encouragement and the appointments are admirable. The services of a visiting medical man are retained and skilled bath attendants act under his direction. The aims indicated above are to be commended—namely, the provision of facilities for taking a course of baths such as may be obtained at health resorts on the continent and in certain of our inland watering-places, with the added advantage of a sea-water supply and of an environment the tonic and bracing influences of which have long been recognised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6609 births and 4450 deaths were registered during the week ending March 30th. The annual rate of mortality in these towns, which had decreased from 21 5 to 18 4 per 1000 in the four preceding weeks, rose again last week to 19 7 per 1000 In London the death-rate was 18 4 per 1000, while it averaged 20 5 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 12 8 in Croydon, 13 0 in West Ham, 14 0 in Birkenhead, and 14 6 in Brighton; the highest rates were 23 2 in Huddersfield and in Newcastle, 23 4 in Birmingham, 28 2 in Liverpool, and 29 7 in Plymouth. The 4450 deaths in these towns last week included 427 which were referred to the principal zymotic diseases, against 370 and 356 in the two preceding weeks; of these 146 resulted from whooping-cough, 120 from measles, 59 from diphtheria, 43 from diarrhœal diseases, 34 from scarlet fever, and 25 from "fever" (principally enteric) No death from any of these diseases occurred last week in Brighton or in Huddersfield; in the other towns they caused the lowest death rates in Plymouth, Norwich, Blackburn, and Halifax, and the highest rates in Birkenhead, Liverpool, Hull, and Gateshead. The greatest mortality from measles was registered in Liverpool, Hull, and Gateshead; from scarlet fever in Preston; and from whooping-cough in Bristol, Cardiff, Swansea, Wolverhampton, Nottingham, Birkenhead, Hull, and Sunderland. The mortality from "fever" showed no marked excess in any of the large towns. The 59 deaths from diphtheria included 16 in London, six in Bristol, six in Leicester, six in Sheffield, and five in Salford. No fatal case of small-pox was registered last week in any of the 33 large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums hospitals during the week ending March 30th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1568, against numbers declining from 2535 to 1598 on the 13 preceding Saturdays. The deaths referred to diseases of the respiratory organs in London, which had been 501 to 332 in the four preceding weeks, rose again last week to 363, but were 78 below the corrected average. The causes of 67, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Salford, Bradford, and 10 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, Hull, and Newcastle.

---

[1] THE LANCET, August 18th (p 493) and Oct. 6th (p 1029) 1900.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·5 to 21·1 per 1000 in the four preceding weeks, rose again during the week ending March 30th to 21·6 per 1000, and showed an excess of 1·9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·1 in Perth and 18·1 in Dundee to 22·8 in Glasgow and 24·0 in Edinburgh. The 678 deaths in these towns included 36 which were referred to whooping-cough, 17 to measles, 16 to diarrhœa, 10 to small-pox, six to diphtheria, four to scarlet fever, and four to "fever." In all, 93 deaths resulted from these principal zymotic diseases, against numbers declining from 122 to 87 in the four preceding weeks. These 93 deaths were equal to an annual rate of 3·0 per 1000, which was 1·1 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had declined from 67 to 38 in the four preceding weeks, further decreased last week to 36, of which 14 occurred in Glasgow, eight in Dundee, five in Edinburgh, five in Paisley, and three in Leith. The deaths from measles, which had been 15, 10, and eight in the three preceding weeks, rose again to 17 last week, and included eight in Edinburgh, five in Glasgow, and three in Aberdeen. The fatal cases of diarrhœa, which had been six and 15 in the two preceding weeks, further rose last week to 16, of which eight were registered in Glasgow, two in Edinburgh, two in Dundee, two in Aberdeen, and two in Paisley. The deaths from small-pox, which had been 20, 24, and 11 in the three preceding weeks, further declined last week to ten, all of which were recorded in Glasgow. The fatal cases of diphtheria, which had been seven in each of the two preceding weeks, declined to six last week, and included two in Glasgow and two in Edinburgh. The deaths from scarlet fever, which had been five and two in the two preceding weeks, rose again last week to four, of which three occurred in Glasgow, where two of the four fatal cases of "fever," were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 171 and 126 in the two preceding weeks, rose again to 126 last week, but were 45 below the number in the corresponding period of last year. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 34·6 and 36·6 per 1000 in the two preceding weeks, declined again to 34·0 during the week ending March 30th. During the 13 weeks of the quarter ending on that date the death-rate in the city averaged 33·6 per 1000, the rate during the same period being 18·7 in London and 22·0 in Edinburgh. The 226 deaths belonging to Dublin registered during the week under notice were 17 less than the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 12, 14, and 15 in the three preceding weeks; of these, 11 resulted from scarlet fever, one from measles, and one from "fever." These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rates during the same period being 1·8 in London and 3·0 in Edinburgh. The mortality from scarlet fever was largely in excess of that recorded in any recent week. The 226 deaths in Dublin last week included 29 of children under one year of age and 58 of persons aged upwards of 60 years; the deaths both of infants and those of elderly persons showed a decline from the numbers recorded in the preceding week. Seven inquest cases and four deaths from violence were registered; and 80, or more than one-third, of the deaths occurred in public institutions. The causes of 14, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons J. F. Hall to the *Arethusa*, and C. G. Matthew to the *Pelorus*. Surgeons: A. Gaskell to the *Barfleur*, B. F. Parish to R.M.A. Headquarters, Portsmouth, and E. T. Meagher to the *Duke of Wellington*.

Fleet Surgeon William Berkeley Drew has been promoted to the rank of Deputy-Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors to be Lieutenant-Colonels:—Alfred O. Geoghegan, Benjamin T. McCreery, John Richard Dodd, George Edward Twiss, Charles George Drummond Morse, Arthur Bowdich Cottell, Thomas Archer, Herbert John Robert Moberly, Alfred Paul Hart, Henry John Barnes, Richard Henry Stewart Sawyer, Walter George Augustus Bedford, Richard Jennings, Stapylton Chapman Bates Robinson, Richard William Ford, George Coutts, William James Baker, Henry Kingston Allport, Edward Butt, Samuel Townsend, Tom Percy Woodhouse, Joseph Gibson, James Havelock Alexander Rhodes, Louis William Swabey, Richard Edward Ricketts Morse, William Rowney, Thomas Rashleigh Lucas, Alfred Goodwyn Kay, William Wippell Pope, Robert Porter, Richard Charles Kirby Laffan, Charles Andrew Pearson Mitchell, George John Coates, Thomas Broderick Albert Tuckey, Frederick Arthur Harris, Francis Augustus Bonner Daly, Alexander Simpson Rose, John Battersby, James Maconachie, Menus William O'Keeffe, Thomas Joseph O'Donnell, Reynolds Peyton Hetherington, Thomas Arthur Dixon, and Walter Croker Thomas Poole.

Captain H. W. Vaughan-Williams, from half-pay, to be Captain, with precedence next below J. M. Buist, vice W. P. Barter, deceased.

SOUTH AFRICAN WAR NOTES.

Major Wyatt, R.A.M.C., is reported to be slightly improved (Bloemfontein, March 27th).

Civil Surgeon Bruce is reported out of danger (March 27th).

Major C. Stonham, R.A.M.C., Lieut.-Colonel A. H. Keogh, R.A.M.C., and Civil Surgeon Green have arrived in England.

THE VICTORIA CROSS.

The Victoria Cross has been conferred by the King upon Lieutenant H. E. M. Douglas, R.A.M.C., for the following act of gallantry:—"On Dec. 11th, 1899, during the action at Magersfontein, Lieutenant Douglas showed great gallantry and devotion under a very severe fire in advancing in the open and attending to Captain Gordon, Gordon Highlanders, who was wounded, and also attending to Major Robinson and other wounded men under a fearful fire. Many similar acts of devotion and gallantry were performed by Lieutenant Douglas on the same day."

TRANSACTIONS OF A GERMAN AMBULANCE AMONG THE BOERS.

Writing under the rubric "Revue des Guerres" in the *Archives de Médecine et de Pharmacie Militaires* for March, Dr. G. Fischer, a junior surgeon in the French army, gives the subjoined table with reference to the mortality from gunshot wounds in the German Red Cross Ambulance which proceeded to South Africa under the charge of Dr Matthiolius in December, 1899

Boer mortality from wounds by—	Cranium.	Face.	Thorax.	Abdomen	Vertebral column	Limbs.	Total.
Artillery projectiles	3	1	—	—	1	2	7
Percentage to wounded	21·0	10·0	—	—	100·0	3·4	7·5
Small arm projectiles	6	1	2	4	2	1	16
Percentage to wounded	44·4	4·5	7·1	15·4	50·0	0·5	6·8

Dr Fischer is also responsible for the statement that at the six engagements specified below the Boer losses amounted to 224 killed and 607 wounded, the proportion between the two categories being as 1 to 2·7 Maggersfontein (Dec 11th, 1899), Tafelkop (March 29th, 1900), Ladysmith (Jan 6th, [illegible] 0), Tugela (Jan 17th–26th, [illegible] 900) (The orthography in

DEATHS IN THE SERVICES

Inspector General Richard Dane, C B, at Southampton on March 27th, aged 88 years He entered the army in 1835 as assistant surgeon, was promoted to surgeon-major in 1855, and reached the rank of inspector general of hospitals in 1868 He served in the Punjab campaign of 1848–49, including the battle of Gujarat (medal), and acted as principal medical officer of the expeditionary force in China in 1858, being present in the various operations of the campaign (mentioned in despatches) On his retirement in 1872 he received the C B and a special pension for distinguished services

Surgeon James Powell Willis, R N, of the Portsmouth training ship *St Vincent*, at Sundayswell, Cork, on March 25th, from typhoid fever after an illness which lasted five weeks The deceased, who was only 29 years of age, was a son of Fleet Surgeon S Armstrong Willis, R N (retired), and received his medical education at the University of Durham, where he took various scholarships and graduated M B (with honours) and B S in 1892 Surgeon Willis leaves a widow and child

The King has given to Major Cathcart Garner, R A M C, His Majesty's Royal licence and authority to accept and to wear the Insignia of the Third Class of the Imperial Order of the Medjidieh, conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered to His Highness

"Audi alteram partem."

THE DUTY OF THE PROFESSION IN REGARD TO LEGISLATION FOR ALCOHOLIC EXCESS.

To the Editors of THE LANCET

SIRS,—Your leading articles on the alcohol question in THE LANCET of Feb 9th, p 410, and March 23rd, p 873, suggest a still further discussion of this medical question—for a medical question it is of momentous import Few medical men can doubt that there are now five medical questions which concern the public health and the race stability more than any others—viz, the ordinary infectious diseases question, the consumption question, the syphilis question, the housing question (which includes the provision of proper playgrounds for our children), and the alcohol question Not one of these can be adequately solved but through the application of scientific facts and principles the import of which the medical profession alone can fully estimate I most strongly concur with you that in regard to the whole alcohol question we as a profession have not taken up the position that our knowledge and opportunities give us, and when we have spoken it has scarcely been with that earnestness which comes of an assured conviction that we are dealing with one of the most dangerous enemies to our modern English race that exists The advances in scientific knowledge in regard to brain physiology and pathology and its mental relations within the past half century entitle us, nay, they should compel us, to utilise that knowledge for the benefit of the public health as well as for the individual patients whom we treat I hope there are few medical men who will not heartily agree with you and Dr William Carter of Liverpool that the alcohol question should now be treated as a part of public and preventive medicine Thus only can we get it subjected to those great principles that have initiated the recent legislation for the health of the community and the stability of the race which are embodied in the Factory Acts the Lunacy Acts, the Workshop Inspection Acts, and the various Acts relating to public health It is chiefly, I believe, by a clear realisation on the part of the public and of politicians that such principles, through which the absolute liberty of the subject is conditioned for the good of the social body and the benefit of future generations, are applicable to the alcohol question that they will embody them into effective laws The medical profession alone can demonstrate this applicability Thus only can the enormous influences of "the Trade" be overcome That great power will fight the mere social reformer, the prohibitionist, and the teetotaler to the death, and hitherto it has fought them all most effectually But cold, hard scientific principles used dispassionately by a profession which has no antagonism whatever to "the Trade," has no personal advantages in the matter, and is obviously acting in the public interests, must surely prevail in the long run Thus only shall we get rid of pettifogging attempts to remedy the alcoholic evils in detail, and be able to put the whole of the legislation in regard to alcohol on as broad a basis of principle as the existing Public Health Acts To a considerable extent the embodiment of the proposals in Lord Peel's report would come up to the ideas of our profession on this subject Here it may be necessary to point out that in educating the public mind and in legislating for the nation in regard to alcohol no practical account need be taken of the Weismann or other such transcendental theories of heredity, or of any such theory of alcoholic "immunity" as was lately developed so interestingly by Dr. Archdall Reid The hard and undeniable scientific facts about the injurious action of excessive alcohol on the brain functions and structure can be as clearly demonstrated as the mutual interaction of an acid and an alkali Whatever theory of heredity may ultimately be proved to be the true one, the fact is demonstrable that the children of the worst kind of drunkards are to a great extent ill developed, neurotic, criminal, feeble minded, or insane, and therefore bad citizens It does not weaken the force of these facts, but rather strengthens them, that the drunken parent was himself probably of a neurotic, degenerate stock, this being one cause of his taking to drink, and that he thus fell an easy prey to the temptations which beset him at every public house or in the social customs of his class When to adverse hereditary influences we have added toxic interference with the germ plasm, a bad environment in childhood, bad and insufficient food, a bad example at home, and unphysiological conditions of life generally during childhood and adolescence, we have a sum of conditions which make for national decay and which call urgently on the State for remedy by every means in its power

If the doubter needs additional facts we can refer him to Professor Kraepelin's recent careful scientific experiments on the *injurious effects* of large, but non intoxicating, doses of alcohol on the mental and motor working of otherwise healthy brains and the extraordinary persistence of some of these effects for long periods after the alcohol has been stopped Such physiological facts will receive sure confirmation through the pathological changes that within the past 10 years our microscopists, by their recent methods of preparation, have been able to demonstrate in the brain cortex of alcoholics—changes affecting the blood vessels, the neuroglia, and the cells Such changes can be seen both in those dying from acute alcoholic toxæmia and in the case of the respectable toper who has lived and enjoyed himself for 20 years since he began to drink too much, all the time getting lowered in mind and morals *pari passu* with his cortical deterioration and in consequence of it

The effects of excessive alcohol in causing insanity, both *de novo* and by bringing out latent tendencies thereto, I can speak about with some confidence after nearly 30 years' experience at the head of a large mixed city asylum. I find alcoholic insanity increasing here in prosperous times, as my friend, Dr. Yellowlees, found long ago in Glamorganshire. It now amounts to 25 per cent. of our admissions. If this is general, surely no social fact should cause a more intense feeling of disappointment to the well-wisher of our British race. That the extra money which might have provided food, luxuries, books, amusements, greater happiness, and longer life to our artisans and labourers should have gone towards brain poison, causing mental disease and degeneration, is surely one of the most biting of satires on our boasted nineteenth century progress. Could any greater human act of folly possibly be conceived? Science has nothing to say against punishing the ordinary responsible drunkard for being found drunk and for any criminal act he may commit while drunk. It has no theories that tend to diminish the responsibility of healthy men to the law. Duty, conscience, accountableness mean just as much in true science as they do in law and ethics. But science does step in and point out that there are special temptations and opportunities to drink which cannot or are not likely to be resisted by certain uneducated or unstable brains in which the faculty of inhibition is weak, and that while such persons might under favourable circumstances in a generation or two get over their brain weaknesses through the natural laws that tend to bring a weak organism back to the ideal, they will, when poisoned by alcohol, go surely on towards mental disease, crime, and extinction—meantime handing down a progeny with all their own tendencies accentuated.

Another thing the medical profession is specially fitted to do, and that is to judge rightly the safe limits of the pleasures and the social and personal amenities which alcohol in physiological quantities may secure, and to pick out the persons who can safely indulge in such pleasures. They fully recognise, through their physiological and medico-psychological studies, that human nature has never in any age or race been satisfied with bread-and-butter, but that it has craved, and always has secured, some stimulant or narcotic in addition to its common food. They can look at this fact from a scientific and brain point of view, not usually being biased or carried away by metaphysical, religious, or ethical standpoints in estimating the significance of such cravings. They can distinguish between a controllable desire and a morbid and injurious craving for such things, whether it be tea, tobacco, opium, or alcohol. They know where safety lies and danger begins. They well know also that men and women largely sin in ignorance when they begin to exceed in the use of such brain stimulants and sedatives, but that excess once begun it is apt to be a case of *facilis descensus Averno.* They also know, as no other men can know, the meaning of that slight mental and moral lowering which results from the habitual over-use in small degrees of stimulants.

This special knowledge throws a tremendous responsibility on our profession towards the public in regard to the alcohol question. But it may be suggested: "If the State or society for its advantage wants to get the benefit of our scientific experience let it ask us for our opinions, and put us in a position to have our views translated into laws." I do not think we can thus get rid of our duty. The State now deals with the alcohol question in a way, and it has created a most profitable monopoly in its sale so that it can further deal with it as it thinks good for the existing community and for the race of the future. If we can instruct the State and make our legislators realise that the advances of scientific knowledge have created a new and an imperative duty in this matter towards the health and well-being of our people, surely we are bound to exert all our influence to secure efficient legislation, just as you point out that Snow and Simon and others of our profession persuaded the State to embody their scientific discoveries in the Acts that provide pure water and air uncontaminated with sewage exhalations for the people. The populace did not make these demands. It was too ignorant at the time, just as it is now, in regard to the scientific aspect of the alcohol question. The State did not go to Snow and Simon. Those men first convinced the medical profession of the truth of their views and then went to the State to tell it its duty. Parliament was profoundly ignorant of the facts and very sceptical. The scientists were "impractical" doctrinaires and the legislation demanded was sneered at as "grandmotherly." We are now in the same position in regard to the alcohol question. We cannot shirk our plain duty in this matter. It is certain, too, that, as in regard to ordinary sanitation, the existence and working of such Acts would be a most important education to the public in regard to the dangers of alcohol. Thus sobriety on principle and conviction would be attained—the highest result of all. Surely we might now reasonably ask something like the following legal provisions.

1. Powers to restrict the liberty of the habitual drunkard and to place his name on a black list or to put him under treatment. 2. Powers to protect children in every reasonable way against alcoholic evils. 3. Compulsory instruction in regard to the dangers of drink and the necessity of physiological temperance to be given in all schools. 4 A strict and even suspicious inspection of all public-houses by a special department of police. It is a most anomalous and irrational thing that dairies, factories, lunatic asylums, gaols, reformatories, workhouses, schools, and many special trades are rigorously inspected by the State, while public-houses, that may do far more harm to society than any of these are left practically uninspected. 5. Provision for a careful inquiry by a public, impartial authority into the character of those who hold licences and sell drink in public-houses before the licence is granted. 6. The punishment of everyone who knowingly sold drink in such quantities the immediate effect of which was to create the condition and crime of drunkenness. 7. Provision for good food and non-intoxicating drinks in all public-houses. 8. A general diminution of temptations to excessive drinking and shorter hours for public-houses. 9. A duty laid on an impartial judicial and medical authority to investigate the causes of any special amount of drunkenness, or disease, or race degeneration the result of drunkenness in any locality, and powers to enforce drastic remedies. 10. Abundant liberty for localities to try methods of supplying the public with drink other than through the ordinary licensed public-house, and to provide counter-attractions in every reasonable way.

I am, Sirs, yours faithfully,

March 30th, 1901. T. S. CLOUSTON.

LEGISLATION AGAINST NATIONAL INTEMPERANCE.

To the Editors of THE LANCET.

SIRS,—Two questions lie at the root of the problem of temperance reform—the question as to whether parental intemperance affects children subsequently born and the question as to whether measures for diminishing or abolishing the use of alcohol are practical. I need not dwell on the first point. It was dealt with at length in THE LANCET of Oct. 14th, 1899, p. 1046. I observe, however, that your correspondent, "M.D., B.S. Lond.,"[1] states that "it is a fact that habits of intemperance in either parent tend inevitably to produce conditions which act unfavourably upon the children and interfere with the healthy development of both mind and body." May I ask him for evidence in support of this statement—which, if true, is of such momentous importance that the whole temperance problem hinges on it? My request has been made many times, but the reticence and silence which have always followed are so curious that I await his reply with unusual interest.

Of late years temperance reform has been tried on a very wide scale in the civilised world. I have ventured to challenge[2] its advocates to indicate a single instance of its successful application—to indicate a single instance in which prohibitory laws have not been followed by increased drunkenness, as well as by a general degradation of the public morals. As yet I have received no reply, and I anticipate none. The most drastic measures having failed everywhere "M D., B.S. Lond." proposes to exclude children and barmaids from public bars. He will perhaps pardon me, but I am irresistibly reminded of the historic lady who tried to sweep back the ocean with a broom. He inveighs against the "firmly rooted belief in the general usefulness of alcohol both as a remedy in disease and as an article of diet," and declares that "it is our duty to put the facts clearly and authoritatively before the public." I cordially agree. But may I add that some knowledge of the biological truths which underlie this matter, as well as of the disastrous failures which have attended all attempts at temperance reform on the lines laid down by your correspondent would be useful also When we cease to push back the ocean with a broom, when we raise the level of the land, then we may be successful

[2] THE LANCET, Feb. 23rd, 1901, p 578.

I am, Sirs, yours faithfully,
Southsea, March 26th, 1901. G ARCHDALL REID

To the Editors of THE LANCET.

SIRS,—The letter of your correspondent, Dr H Laing Gordon, would have received my attention, but with "M D, B S Lond" I quite agree in regarding it as not at all helpful. I believe I am acquainted with the recent researches in alcohol and my conclusions, as stated in THE LANCET of Feb. 23rd, p 578, represent, I believe, the correct modern view. Your columns, Sirs, cannot possibly be thrown open to the consideration of any subject more vital in importance, for if drunkenness could be largely diminished by legislative or other action the greatest hindrance to further sanitary advance would be removed and the general death rate might fall to 14 per 1000, for, as it has been observed, the deaths from intemperance have risen from 45 per 1,000,000 of those living to 77 per 1,000,000 Now, Sirs, the medical profession has reduced the death rate of the country to its present level, and it alone can, and I believe will, break down this greatest hindrance also There is now a bitter cry throughout the country from the laity to our profession for help and concerted action Declarations by the profession as a whole have been made in the past upon subjects with such vital relations to the welfare of nations and with the most successful results Is not the present time opportune for such? I will gladly subscribe to any fund required to promote concerted action

I am, Sirs, yours faithfully,
Lightcliffe, Yorks, March 23rd, 1901 ASPINALL MARSDEN

THE RECENT EPIDEMIC OF TYPHOID FEVER IN SOUTH AFRICA.

To the Editors of THE LANCET

SIRS,—In the recent discussion on this subject before the Clinical Society of London, Dr Howard Tooth[1] in his very able paper gave expression to the opinions of the majority, at all events, *of medical men who have had opportunities for* observation during the epidemic in South Africa The fact of water being the chief source of infection is beyond question Even water derived from very deep levels has been shown to contain pathogenic organisms In one instance, at all events, water taken during the sinking of a mine shaft at a level of nearly 200 feet was found to contain streptococci, and on investigation this was found to be infected from surface water which had become contaminated *by passing through disused filled in latrine trenches some* hundreds of yards away Filtration through the soil, therefore, had had but little effect upon the water and, as the event proved, the water induced a serious outbreak of enteric fever amongst those who had made use of it for drinking purposes, from which it may be assumed that the bacillus typhosus was also present

As Dr Tooth points out the spread of enteric fever by dust has received far less attention than it deserves That infective material does become dried and driven about as dust is beyond dispute This was proved on several occasions at Johannesburg last year by exposing culture plates during dust-storms It is difficult enough to devise any certain and practicable method for purification of infected water, it is impossible entirely to obviate risk of infection by dust. In some directions, however, it is possible and in one in particular *much might be done which is not done at present* It is quite impossible to avoid the transference of patients sick from enteric fever in various stages, or from dysentery, or from the various forms of diarrhœa which are so universal in South Africa and the precise nature and relationship of which are so obscure During the transport by train it is obvious that the lavatory accommodation is strained to the utmost The waste pipe from the water closets discharges directly on to the line, and except in the case of lying down patients, who are by no means the only infective ones, no method of sterilisation is adopted In the neighbourhood of stations sick trains are constantly delayed on sidings One that I took down country, for instance, was delayed on a siding all night, 68 patients, all either enteric fever or dysentery cases, being on board The condition of that siding in the morning can be better imagined than described There was doubtless infective material enough in that one spot properly distributed to spread enteric fever and dysentery throughout South Africa This constant infection of the line during many months supplied ample material for the distribution of disease by dust There was probably not one single station or siding from Cape Town to Pretoria in which enteric fever and dysentery cases might not be found The remedy for this infection of the railway track is obvious and simple If instead of the waste pipe discharging on to the permanent way tanks containing some efficient antiseptic were provided beneath the lavatory, which could be emptied and the contents destroyed as opportunity offered each day, one very constant and active source of infection might be greatly lessened if not entirely removed

Flies unquestionably formed almost as serious a means of distribution of infective disease as dust They swarmed in *the latrines and were the pest of the enteric fever tents*; on the surgical side of the hospital they were very little trouble comparatively Food left uncovered even for a minute during the summer time was quickly black with flies and there can be no shadow of doubt that many must have previously been upon infective material As Dr Tooth very truly remarks, the wonder is not that the epidemic was so severe, rather is it a matter of congratulation that it was not more so, considering how many unavoidable causes were at work

The causes of the spread of the disease, at all events on active service, being in many cases wholly unavoidable, the success or otherwise of protective inoculation becomes of vast importance The statistics which have so far been forthcoming are, to say the least, unconvincing Moreover, *those emanating, or which will shortly emanate, from the* military hospitals will, it is to be feared, be of little or no scientific value whatever The reason is not far to seek A very large number of cases stated to be those of enteric fever proved ultimately not to be so When first seen there was doubtless every reason for believing that the diagnosis was correct, but when transferred, as such cases often were, to another hospital, a few days' observation proved that the attack of fever, whatever may have been its nature, at all events was not enteric The sick reports which arrived with these cases were marked "enteric" and also "inoculated" or "not inoculated" as the case might be In many instances no official alteration of the original diagnosis was made Since the statistics are, or will be, largely if not wholly compiled from these sick reports it is obvious that it does not need very many of these erroneous papers to vitiate any statistics that may be drawn up from them That it should be well nigh impossible to avoid these clerical errors on active service is obvious to anyone who knows the conditions under which the work has to be carried out They are, after all, only errors on paper and no patient ever suffers as a result of them At the same time, it is only right to point out this serious source of error when one hopes for scientific conclusions as to inoculation for enteric fever to be drawn from the statistics that will ere long be published If this source of error can be eliminated then of course the statistics become of real value and some degree of finality may be attained I am unable to quote figures at the present time, but Dr Pershouse, who was head of the enteric division of No 6 General Hospital, and who had many hundreds of unquestionable cases of enteric fever through his hands, assured me that after very careful study of the question and from very carefully kept records he was unable to give a definite opinion in favour of inoculation It is essential that not only should the mortality of authenticated cases be recorded but also that the incidence of the disease in the inoculated and uninoculated should be shown

The question is one of such paramount importance that it is sincerely to be hoped that reliable evidence will ultimately be forthcoming

I am, Sirs, yours faithfully,
H TEMPLE MURSELL M B, F R C S Edin,
Late Civil Surgeon British Forces, South Africa.
Weymouth street, W, March 29th 1901

"THE TEACHING OF ANÆSTHETICS"

To the Editors of THE LANCET

SIRS,—In Dr Frederic Hewitt's letter in THE LANCET of Jan 19th, p 212, he attacks me for hampering the important question of making the teaching of anæsthetics a recognised part of the medical curriculum by introducing side issues. On the importance of the question I am in full accord with Dr. Hewitt, but what he terms side issues are merely further stages of the discussion. As soon as it is admitted that the medical curriculum should include anæsthetics, the next questions to be decided, and they are not side issues, are, what is the best method of instruction, and what anæsthetic is safest in the hands of the average medical practitioner? Students are already overburdened with lectures and examinations, and such means are quite inadequate to make them skilful chloroformists. This can only be done by a regular course of clinical training in a hospital. The plan which we have found to work well is to make every student give chloroform for a stated period. While he is performing this duty no one is allowed to interfere with him except the operating surgeon, but careful and accurate notes are taken of every detail throughout all his administrations. In this way he acquires the habit of responsibility, and the onlookers become familiar with the method of administration which thus becomes traditional in the school, so that when the student's turn comes to act as chloroformist he is perfectly familiar with sound principles, and very soon acquires the experience, from a large number and variety of cases, which makes him a skilled anæsthetist. In London there is no practical teaching in anæsthetics worthy of the name. In most hospitals anæsthesia is produced in a side room, the patient is only brought into the operating theatre when he is "over"; the students do not even see, or, as they ought, carefully watch and take notes of the process, and the teaching literally amounts to "handling" the ether inhaler occasionally for a few minutes. In Hyderabad we find a month of clinical training more than sufficient to render the average student capable of administering chloroform, the only anæsthetic we use, with a safety which is unattainable even by ether. This is clearly demonstrated by our statistics which show no deaths in dental operations under chloroform during the last 15 years, while those of Dr. Hewitt show that in the same period there were in Great Britain 10 deaths from the other anæsthetics which he advocates in preference to chloroform.

---

[1] THE LANCET, March 16th, 1901, p. 769.

Table of Dental Anæsthetic Mortality (Compiled from the Statistics of Dr. Hewitt and Lieutenant-Colonel E Lawrie, I.M.S.).

Statistics.	Locality.	Period.	Mortality.	
			From chloroform.	From other anæsthetics
Dr. Hewitt's	Scotland	15 years	12	2
	England and Wales (excluding London)	15 years	15	6
	*London	15 years.	—	2
Lt.-Col Lawrie's	Hyderabad	15 years.	—	—

* Chloroform was seldom if ever used in London.

These figures should be clear proof that chloroform properly administered—i.e., on Syme's principles and in the Hyderabad method—is the safest anæsthetic, and if we in Hyderabad can teach the average student and nurse to be thoroughly efficient in a month there is no reason why the average English medical student, who will eventually become the average practitioner, should not attain the art in an even shorter period. In fact, not only the average medical student, but the average dental or midwifery student, is quite capable of learning the proper method of administering chloroform. If this was done and it was known that chloroform could be given by every doctor and dentist without danger and with little or no additional expense—unless the patient desired to indulge in the luxury of a specialist—the result would be an enormous increase in the numbers of patients anæsthetised and an immense alleviation of suffering throughout the length and breadth of England.

Dr. Hewitt attempts to explain away our admitted success in practice in various ways but fails completely. For his ill-defined theory of the influence of cold and damp on anæsthesia he can produce no scientific evidence. Would he venture to assert that chloroform is more dangerous at Lahore in the cold weather with a mean temperature of, say 45° F., than in the hot weather when the mean temperature is over 100°? Is it less risky in Simla with an altitude of 7000 feet than in Calcutta which is almost at sea-level; in Jerusalem than in Jericho? Personally I have never found any difference was caused by variations of temperature or humidity, or even by the change from England to India. Nor are we, as he insinuates, afraid to use chloroform properly. Certainly our doses are proportioned to the needs of our cases. To produce complete anæsthesia or narcosis in every case of tooth extraction is to abuse the drug and cause unnecessary inconvenience, and perhaps sickness, to the patient. On the other hand, we do not habitually endanger our patients' lives by pushing chloroform "beyond the point where the corneal reflex disappears," which is the system Dr. Hewitt advocates. When that point is reached the patient is completely narcotised, and to push it beyond it is to keep him on the very verge of being overdosed, to approach if not to enter the region of danger. But the assertion that we do not produce complete anæsthesia when the operation renders it necessary is as untrue as it is ridiculous, and I should like to know Dr. Hewitt's authority for the statement. Nor, again, do we rely on the special gifts for anæsthetising with which Dr. Hewitt so generously credits me. I may say that I rarely give chloroform personally; at my operations I do the surgeon's work, and leave the anæsthetising to students and nurses of no special endowments. Yet my record in surgical as well as dental operations is, with one regrettable exception, unbroken, and it is they who have kept it so, just because they have had clinical training in the right method.

Moreover, the value of our methods must, I submit, be judged by our own statistics, which are of real scientific value, as each case included represents a uniform plan of administration, and not by the loosely compiled figures from which Dr. Hewitt draws the illegitimate inferences which form the latter part of his letter. He assumes in them that in all operations in Scotland, in the 15 years from 1880 to 1895, chloroform was administered on Syme's principles and the Hyderabad methods, and in all operations in England on other principles and methods, and he urges that the high dental anæsthetic death-rate in Scotland condemns our position. In the first place, Syme's principles are by no means universal in Scotland nowadays and the improved Hyderabad methods are almost unknown. Besides, are not many English practitioners trained in Edinburgh? Have not several Scottish practitioners gone out from the London hospitals? May not some of the others have hearkened to the voice of Professor Annandale, who teaches London methods from Syme's chair? What was the method adopted in the Scotch hospital to which Dr. Hewitt refers as having nine deaths in one year? When did these accidents occur? In fact, locality is no proof of the method adopted, and as the statistics are based on a definition of method by locality they are valueless. Dr. Hewitt's arguments are, however, worthy of their foundation. What is the use of calculating, as he does, the ratio of deaths to population and not to the operations in which the various anæsthetics were administered? The latter is the only percentage of value, and even then the method of administration must be carefully specified before figures can tell either for or against any particular plan. Dr. Hewitt's conclusion is a fitting climax. It is that I disregard the risks of chloroform. Carelessness of life is a strange accusation to bring against me, when the method I advocate in the hands of students and nurses has in 15 years caused no death in dental operations, while Dr. Hewitt's have on his own showing produced "*only* 23." I can assure him that I am fully alive to the risks to which his methods subject his patients, and that the only thing I do disregard and utterly deny is the direct action of chloroform on the heart, behind which he and his fellows shield themselves and the disastrous results of their teaching.

In conclusion, I have great pleasure in giving Dr. Hewitt information on a point on which he is apparently ignorant. Although there is no coroner's inquest in Scotland there is an efficient substitute in the inquiry before the procurator fiscal, and it is no more likely that accidental deaths under chloroform escape notice in Scotland than in England. Be this as it may, unless and until it is shown that the Hyderabad methods were adopted in each case it is difficult to understand how Dr. Hewitt's position could be strengthened by a fuller record of the chloroform deaths in Scotland, any more than it would be by a more complete record of the deaths from ether which unquestionably escape notice in

London where coroners' inquests abound Both would prove that his position is an absolutely false one, brought about by the deplorable attitude which he and his fellow anæsthetists still maintain towards the work of the Hyderabad Commission. Dr Hewitt affects with some show of confidence to shelter himself behind the "scientific world" in this matter, but even he cannot have failed to notice that, though the world of science is particularly well able to speak for itself, it has been singularly reticent on the subject of anæsthetics ever since the Cambridge contingent of its representatives cut such a very poor figure at the great meeting of the British Medical Association in Montreal

I am, Sirs, yours faithfully,

EDWARD LAWRIE

STATISTICS OF OPERATIONS ON THE KIDNEY

To the Editors of THE LANCET.

SIRS,—In an endeavour to make a collection of renal operations performed up to the end of the last century I am desirous that the statistics should be as complete as possible and made to include not only those cases the records of which are known, but also unpublished cases. May I therefore venture through your columns to ask operators to assist me by sending to me a complete list of their operations up to Dec 31st, 1900, giving particulars in the following order :—(1) Number; (2) date of operation; (3) name of operator, and if the case has been published, where, (4) sex and age of patient; (5) nature of disease; (7) duration of dise *as ultimately determined*, (9) *ultimate result*.

Fourteen years ago I made a similar appeal and in response received records of a large number of valuable unpublished cases, also details as to the ultimate result of many others the earlier history of which had been made known Encouraged by the hearty cöoperation formerly accorded I now appeal to a greatly increased field of workers for help in demonstrating the position to which renal surgery has attained I am, Sirs, yours faithfully,

DAVID NEWMAN

Royal Infirmary, Glasgow, March 21st, 1901.

PS —Schedules will be supplied on application to my resident assistant at the Glasgow Royal Infirmary —D N

"THE ORGANISATION OF THE PROFESSION."

To the Editors of THE LANCET

SIRS,—I should like to say a few words on the above subject which is introduced in THE LANCET of March 23rd, p 894, by "A General Practitioner." It is over two years ago since the medical men practising in the eastern valley of Monmouthshire found it necessary to organise themselves into an *association* chiefly—with the object of getting better pay, and to that end a circular was printed and sent to the various *collieries* and works by the *surgeons* attending them Up to that time the medical attendant was paid at the rate of 2*d*. in the £ of the weekly earnings, and the medical attendant was to provide medicine, medical attendance, undertake all accidents *and operations* and provide appliances to the workman, his wife, and family. Midwifery was the only thing paid specially for, and that was expected to be attended for a fee of *10s 6d* irrespectively of the nature of the case or the distance away. Immediately the notices went forth to the various works from the doctors asking for the advance of 1*d* in the £ an angry growl rose from the mass of workmen and many meetings were held, the collier especially being the most dissatisfied and endeavouring to make a good bargain for himself by stating that if he advanced the doctor's pay *1d* in the £ he must have a *quid pro quo* in the shape of *linseed* meal, cod liver oil, and free midwifery, thoroughly disregarding the fact that we had attended all through the five months' coal strike without a farthing remuneration and, as we had pointed out in our circular letter, that the advance in assistants' salaries and other things connected with the profession made it imperative that our pay should be increased We made up our minds distinctly that we could not supply cod-liver oil and linseed-meal, neither would we give *free midwifery*, although we knew that in the western valley and some other places in the South Wales coal district these three things had been conceded, as well as free attendance on venereal diseases We had met the British workman with his own weapon and, strange to say, he did not appreciate it—viz, a trade union, and the only thing we had to fear was the introduction of strangers into our midst This was threatened, and one of our members acting rather precipitately resigned His resignation was accepted and an advertisement was inserted in a local paper for a successor to his appointment, and, notwithstanding the fact that by a counter advertisement we asked applicants to communicate with our secretary before applying for the post, no less than 25 medical men made application for the position, which I may add was only a very small affair In the organisation of the profession what is required is that medical men, and the junior members especially, should band themselves together in one union to resist the great tendency there is to reduce our remuneration The junior members should stand by and allow us to fight the battle which in the years to come will be for their benefit During the past two or three years the junior members have benefited in a financial way by the action of their seniors, and if they will only help us by keeping aloof from applying for posts they know to be vacant in consequence of some disagreement with the original *holder until they know the exact position of affairs* they will benefit the profession at large and raise our status socially I may add that after several months of hard fighting we gained the 1*d* advance we asked for without supplying free cod-liver oil and linseed meal, but we had to make a concession with respect to the midwifery, inasmuch as we agreed to attend any workman's wife in her confinement for the usual half guinea providing we were engaged beforehand and a proper nurse were in attendance; but, at the same time, if any woman was being attended by a midwife and any difficulty arose that she could not manage we agreed to give free attendance This was called emergency midwifery This arrangement has now been going on nearly two years and works very well —I am, Sirs, yours faithfully,

S BUTLER MASON, M R C P Edin, &c.,
President of the Eastern Valley Medical Association, Monmouthshire

Pontypool, Mon., March 20th, 1901

DEAFNESS IN BOARD SCHOOL CHILDREN.

To the Editors of THE LANCET

SIRS,—The question of diminishing the amount of deafness in children through the agency of school boards having been raised in THE LANCET of March 16th, perhaps the method adopted in the Halifax schools, though without any claim to originality, may have some interest Each class is visited by the medical officer for this purpose, and all "mouth-breathers" and children thought by the teachers to be deaf are examined by him Printed notices are subsequently sent to the parents of those suffering from adenoids advising them to seek medical treatment either privately or in hospital. In a few cases of otorrhœa a similar notice is sent, but in the majority of these cases the parent is simply warned of the dangers of the condition and advised to syringe the ears daily. Doubtless it would be better to have these cases also under medical supervision, but now and until the poorer classes regard otorrhœa more seriously advice to this effect would be largely thrown away and the moral effect of the notices gradually destroyed I may add that with the increased attention paid to breathing exercises and the repression of mouth breathing it is hoped that the number of adenoid cases will be much diminished The method is no doubt crude but it certainly results in the "cure" of a fair number of cases and a great diminution in the number of offensive aural discharges; it gives rise also to an increased disposition on the part of parents to seek treatment for their children in ear affections which they formerly regarded as of little moment or beyond remedy, and while there are obvious objections to an educational body taking up the actual treatment of disease the education of children or their guardians in the importance of personal hygiene may fairly be claimed as one of their duties

I am, Sirs, yours faithfully,

T H HUNT, M D Lond,
Medical Officer to the Halifax School Board

March 20th, 1901

BEER-POISONING

To the Editors of THE LANCET

SIRS,—Those who drink beer have been rather startled of late by ascertaining that there are disease and death in this wholesome beverage, arising from the introduction of arsenic in its manufacture. But it is not equally well known that there are many sufferers from lead poisoning who have to thank their beer for this often lamentable disease arising in its distribution. I have had a poor woman in hospital for many weeks, not only suffering from dropped wrists, but also from paralysis of both legs, from this cause. The lead is introduced by the employment of lead pipes to convey the beer from the beer-barrel to the beer-pump. Woe betide the unfortunate beer-drinker who frequently has the first "draw" in the morning under these circumstances, for lead-poisoning is sure and death not unheard of. Lead pipes should be prohibited for such a purpose.

I am, Sirs, yours faithfully,

Rugby, March 30th, 1901. CLEMENT DUKES.

THE CASE OF AN ELECTION.

To the Editors of THE LANCET.

SIRS,—In September last a vacancy was advertised for a physician to out-patients at the above hospital. With two other candidates I applied for the post. On Nov. 14th the secretary of the hospital wrote to me that the Committee of Management had elected me. My day of attendance was settled, I took up my duties in the following week, and I intimated to you the fact of my election, which you duly announced. I was subsequently instructed to attend at physicians' operations on two days a week and on emergency calls, which I proceeded to do, assisting at the request of individual members of the staff. I further undertook by request additional temporary out-patient duties. Proofs of the hospital out-patient letters with my name printed thereon were submitted to me for final approval and correction and on Dec. 10th I attended a meeting of the Medical Committee, of which the secretary of the hospital had given me official notice.

Now comes the extraordinary sequel. On Dec. 12th the secretary of the hospital wrote informing me that the minute referring to my election was not confirmed, that the matter therefore stood over for the present, and that he understood a member of the staff would write to me respecting my attendance. On the same day the secretary of the Medical Committee wrote that he had been asked by his colleagues to inform me that as my election was not confirmed it would not be necessary for me to attend in the out-patient department or at operations. In consequence of these letters I at once ceased to do so. On Dec. 21st the secretary of the hospital wrote in reply to me that the non-confirmation of my election left the post vacant; that therefore I was purely a candidate as before and as such not entitled to take part in the work of the institution.

On Jan. 23rd, 1901, he wrote that in consequence of legal opinion the Committee of Management had resolved to take up the election at the point of the reception of the Medical Committee's report on Oct 23rd. Though I have received no official intimation, I understand this took place on Feb. 12th, resulting in the election of one of the other candidates. From the preceding facts, it must be admitted that I am placed in a very anomalous position. I received every proof anyone could possibly expect to receive of my appointment as physician to out-patients at the Samaritan (Free) Hospital for Women and Children On the other hand, I am led to believe that a fresh election has taken place, and another appointed to my post—and that through no fault of mine.

I am, Sirs, yours faithfully,
JOHN A. SHAW-MACKENZIE, M.D. Lond.

Grosvenor-street, W., April 2nd, 1901.

"THE ELIMINATION OF ARSENIC THROUGH THE HAIR."

To the Editors of THE LANCET.

SIRS,—The paper on the Elimination of Arsenic through the Hair in THE LANCET of March 23rd, p. 854, has recalled to my mind some experiments which I made many years ago in conjunction with the late Dr. Bence Jones on the rapidity of the diffusion of substances into, and out of, the animal tissues. Among other substances, we experimented with chloride of lithium, the diffusion of which into, and out of, all the organs and tissues of the body can be traced with remarkable facility. At first I had come to the conclusion that lithium diffused also in the hair. On consideration, however, it struck me that there were at least three possible sources of the lithium I had found in the hair: (1) direct diffusion into the hair; (2) absorption from the perspiration of the skin of the scalp; and (3) absorption from the hand passed through the hair. Accordingly, I carefully isolated some locks of hair by wrapping them in waterproof material, thus preventing absorption by either of the last two possible means. In the hair thus protected I never found lithium, and thus came to the conclusion that lithium did not diffuse directly into the hair. My experiments were not carried on long enough to decide whether or no lithium could be found in the hair grown during the time lithium was taken, as that question lay outside the scope of the inquiry. The question therefore arises, Where was the arsenic found, in the old or only in the new growth? If in the former, were any experiments similar to that described, made?

I am, Sirs, yours faithfully,

Howick-place, S.W., March 27th, 1901. A. DUPRÉ.

To the Editors of THE LANCET.

SIRS,—With reference to the interesting paper on the Elimination of Arsenic through the Hair by Dr. E. Knecht and Mr. W. F. Dearden and your comments thereon[1] may I be allowed to point out that this has been known for some years? As far back as 1891, at any rate, Professor Brouardel in his lectures on medical jurisprudence, insisted on the importance of examining the hair and nails of exhumed bodies for arsenic in suspected cases of poisoning. For all I know the fact that arsenic is stored up in the hair and nails may have been observed long before 1891. Dr. Knecht and Mr. Dearden's independent researches, however, are valuable in directing attention to a point of medico-legal importance. I am, Sirs, yours faithfully,

GEORGE PERNET.

Upper Gloucester-place, Baker-street, N.W.,
March 25th, 1901.

To the Editors of THE LANCET.

SIRS,—With respect to the article on the Elimination of Arsenic through the Hair, contributed to THE LANCET of March 23rd, p. 854, by Dr. E. Knecht and myself, I should like to make an important correction. In line 31, column 1, instead of "Scales are but rarely met with," one should read "*Scabs* are, &c." It is well known that scales are not at all uncommon in cases of chronic arsenical poisoning. I very much regret that I should have failed to notice the error when correcting the proof.

I am, Sirs, yours faithfully,

Crumpsall Park, Manchester, W. F. DEARDEN.
March 26th, 1901.

THE

ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 821.)

The Formation and History of the Gateshead Medical Association.—Defeat of the Attempt by the Friendly Societies to Create Female Lodges.—Increase of Subscriptions Paid by Adult Males.—The Subscription to Private Family Clubs Increased.—Insurance Companies Kept at Bay.—Proceedings against Unqualified Assistants.—Absolute Unanimity Secured.—Active General Propaganda Work.

IN describing the efforts made to organise the members of the medical profession in the counties of Durham and Northumberland the history of the Gateshead Medical Association should have been given first had I taken these organisations in their chronological order. On the other hand, the Northumberland and Newcastle Medical Association should have come last instead of first on the list, for it was constituted at the most recent date. But there was practical utility in calling attention at the earliest moment to those localities where a struggle was actually taking place. Now, however, that these more urgent events have been related it remains to render honour to whom honour is due by giving the history of the parent society. The first historical date in regard to the organisation of the profession in the counties of Durham and Northumberland is Sept. 22nd, 1896. On that occasion the Gateshead practitioners were invited to meet in the private house of one of their number to discuss what steps, if any, should be taken to elect Direct Representatives to the General Medical Council. Out of a possible attendance of 36 practitioners 16 were present and they agreed to take action in regard to the constitution of the General Medical Council. Then towards the end of the meeting someone inquired whether it would not be advisable to try to form an organisation for the special purpose of dealing with ethical and economical questions. This suggestion was so warmly approved that a small temporary committee of four was then and there appointed so as to prepare a scheme and to convoke a general meeting of the entire profession. This meeting took place on Oct 6th following and 18 practitioners attended. The proposed rules then submitted were very short and simple, but they nevertheless gave rise to a lengthy discussion, and this somewhat ardent debate served to reveal the need of an organisation on the lines proposed, and it also showed the eagerness that prevailed among the Gateshead practitioners to take part in such a movement. No line of policy was indicated beyond the decision that the new association was not to be a scientific society but was to deal exclusively with economical and ethical questions. Even at this early period it was agreed that there should be a black list, and that when the association adopted a line of policy any member who did not carry out such a policy should be expelled. After a long discussion the rules were adopted and the Gateshead Medical Association was formally constituted. Dr. William Mearns was elected its president and Dr Alfred Cox its honorary secretary and treasurer, and one member was added to these two so as to form an executive. For about two years these three gentlemen did all the executive work of the association. Simplicity, the avoidance of all complications in management, was their constant aim.

---

[1] THE LANCET, March 23rd, 1901, pp. 854 and 878

The general situation at that time—namely, towards the end of the year 1896—was not complicated. The town was not troubled by provident dispensaries or medical aid associations. There was, however, the threat that small business insurance companies including medical aid as a sort of decoy duck might be introduced at Gateshead, and the friendly societies were anxious to create female lodges. The first line of policy agreed upon was that the association should resist any attempt to make matters worse. Thus, early in the proceedings a resolution was passed by which all the members pledged themselves not to accept the post of medical officer for a female lodge of any friendly society. Then at the second meeting held by the association, on Dec. 1st, 1896, it was decided not to take any juvenile lodges unless the juveniles paid at the same rates as the adults. This was a bold decision, for at Darlington and other neighbouring towns there were juvenile lodges in existence where the children were paid for at the rate of only 1*s*. 6*d* per annum.

At this time the Rechabites had approached their medical officer and asked him to take the families of the members for 2*d*. per week, which, together with the 3*s*. per annum the member himself paid, would make 11*s* 8*d*. per annum for the entire family. These families also were to be accepted without any sort of medical examination and might therefore include chronic invalids. The medical officer in question had refused these terms and had consequently been discharged. This constituted the first practical problem with which the newly-formed medical association had to deal. 23 members were present when this question was discussed and they unanimously adopted a resolution stating that, in view of the fact that the position of medical officer to a lodge was accepted mainly as a means of securing an introduction to the families of the members, no member of the association should consent to act as medical officer to a lodge which had a family club attached to it. The Rechabites now set to work and canvassed all the medical practitioners established at Gateshead. Some half-dozen enthusiastic members of the Gateshead Medical Association, however, had been even more active. Between the first and the second meeting held by this association they had sent circulars or paid personal visits to all the practitioners in the town and had succeeded in enrolling every medical man as a member of the association, and consequently these all rejected the overtures made by the Rechabites. More than this, the Rechabites having discharged their medical officer, the rule that no new appointment was to be accepted on the old terms now came into force; therefore not only did the Gateshead practitioners refuse to have anything to do with the family clubs but they would no longer attend the adult male Rechabites for 3*s*. a year as formerly, and the latter were compelled to pay their new medical officer 4*s*. a year. The fact that they did not return to their old medical officer did not cause any difficulty, as the latter was not anxious to continue this sort of work—indeed, their new officer was also tired of it at the end of three years and resigned his office. Having thus again to change their medical officer the Rechabites made another effort to introduce family clubs. They thought that after a lapse of three years the discipline of the medical association might have become less rigorous, and at first it seemed as if this was the case, for a practitioner did accept their offers. Of course remonstrances were made, and this gentleman explained that he had forgotten that the matter had been discussed three years previously, but he would at once conform to the decision then taken. He therefore wrote to the Rechabites and gave in his resignation, explaining that he could not act against his fellow-members of the profession. In face of this failure the Rechabites definitely abandoned all hope of establishing family clubs and kept the medical officer they had just appointed, paying him 4*s*. to attend only to their adult male subscribers.

To return to the meeting held on Dec. 1st, 1896. Mr. J. Todd then introduced the whole question of friendly society work, pointing out that the 3*s*. per annum that their members paid for medical attendance was not enough. All agreed to this, but there was considerable disagreement as to what should be done. The more buoyant were for immediately organising a general strike against the friendly societies, while others were more timid and suggested careful and patient preparation, and fears were expressed that the friendly societies would establish a medical institute and employ a medical man exclusively as their servant. Ultimately it was decided that a circular should be sent to all the friendly societies asking them to appoint a deputation to discuss the question of remuneration in a friendly manner with the representatives of the medical profession. Then it was discovered that there was no list existing of these societies and no one knew how many there were. Consequently, it was decided that everyone should send circulars to those societies with which he was personally acquainted and thus it was ultimately ascertained that there were 92 or 93 lodges in the town. It was subsequently agreed to urge that medical officers should not be dismissed without due notice. As matters then stood medical officers were re-elected every six months, but if not re-elected they were summarily dismissed.

It was in March following that 60, or about two-thirds, of the lodges sent delegates to meet the representatives of the medical profession. The other lodges took no notice of the circular which they had received. There were nine medical men present and about 120 delegates of the friendly societies. The latter listened carefully to the statements made by the medical practitioners. The discussion that followed was amicable, but the men firmly adhered to their belief that 3*s*. a year was a sufficient payment. Several among them, it is true, recognised that by itself it would be insufficient, but that this was more than compensated by the advantage of attending for ordinary fees the families of the members. It was, however, admitted that when the medical officers complained of being dismissed without notice they had brought forward a genuine grievance.

Subsequently the friendly societies held a meeting among themselves to discuss the points raised by the medical men, and they then decided in a formal manner that they could not see their way to increase the subscription for medical attendance to 4*s*. In face of this refusal the members of the Gateshead Medical Association were about evenly divided, one half urging a strike while the others wanted to follow a more prudent course. The latter policy was adopted and the members contented themselves with signing a pledge that if a lodge changed its medical officer or a new lodge came into existence they would not accept the new appointment for less than 4*s*. Some of the members, however, decided to ask for the increase at once. Some were successful, some failed altogether, and some obtained half of their demand—namely, an increase from 3*s*. to 3*s*. 6*d*. per year instead of 4*s*. Altogether there are now of the old and new lodges about 10 or 12 which pay the 4*s.* Some of the younger practitioners objected to the policy pursued on the ground that it gave them no prospect of getting an appointment, as the lodges would prefer to retain their old medical officers at 3*s.* rather than to engage a new medical officer at 4*s.* The young practitioner and the new-comer thus seemed to labour under a double disadvantage. There was the natural and legitimate disadvantage of his position as a junior practitioner and the artificially imposed disadvantage that he must charge 4*s.* for work which his seniors did for 3*s.* Fortunately actual experience showed that when a lodge was dissatisfied it was not the question of having to pay 1*s.* more that prevented them from changing their medical officer. The normal rate of vacancies was not altered, though every such change had to be followed by increasing the annual subscription from 3*s.* to 4*s.*

The next step taken was to establish a hard and-fast rule where none had previously existed that a charge of at least 6*d.* should be made for all extra certificates given. During the year 1898 another lodge had occasion to change its medical officer. As a medical practitioner had just established himself in the town only a few days previously and did not even know that the medical men of Gateshead had formed an association the lodge approached him. He was only just starting practice, so he willingly accepted the lodge at the lower terms; but he was soon informed of the situation and, to his honour be it said, he at once resigned his post, saying that he would never do anything that was against the interests of his own profession. The lodge, thus disappointed, now sought for and found another weak point in the armour of the Gateshead Medical Association. One of the members of the association had a branch practice at a colliery outside Gateshead. His assistant started practice on his own account near this colliery, and tried to get the miners to be his patients. This was considered to be so unprofessional that several members of the Gateshead Medical Association threatened to resign if this individual was accepted as a member of their organisation. Thus it happens that there is just one medical practitioner in the neighbourhood of Gateshead who is not a member of the Gateshead Medical Association. The lodge thereupon fell back upon this one practitioner, but though he accepted their terms they soon found that he lived too far away to attend properly upon their members, so that they had to give him up and were compelled finally to appoint a member of the Gateshead Medical Association and to pay him the 4*s.* This was the last attempt at resistance. On one subsequent occasion a member of the association by mistake offered to take a lodge at 3*s.* 6*d.*, but, discovering his error, he at once wrote to say that he would not take less than 4*s.* In the meanwhile, however, the lodge had met and some of the members voted against him. Thus it will be seen that the workmen themselves are beginning to understand, and to approve of, the position taken up by the organised members of the medical profession. This is an important, a significant, and a hopeful incident.

The National Deposit Friendly Society sought to establish a branch at Gateshead just about the same time as the Medical Association was formed. Early in 1897 the medical practitioners discussed this society at length. Some of the members thought that it was a fair society because it did not pay a fixed yearly sum and allowed its subscribers to select their medical attendant. On the other hand, it was objected that there was no wage-limit and that the National Deposit Friendly Society appealed to tradesmen rather than to workmen. Its general introduction, it was said, would tend to lower medical fees; then it was a comparatively new society, and there was no need of yet another organisation seeking to act as an intermediary, a third party, between the medical men and their patients. It was therefore decided not to accept their terms. The National Deposit Friendly Society nevertheless sent agents who endeavoured by every means to make the medical men reconsider their decision. They proposed that the medical practitioners should charge whatever fees they thought proper and the members would pay half and the society the other half. This, however, meant that the medical practitioners must first sign the documents of the society, which would be shown to prove that the medical men approved of the institution. Finally, it was resolved that no signatures should be given and no terms accepted, and that if any members of the National Deposit Friendly Society applied for medical advice they must be treated as ordinary private patients.

The next question raised was that of the family clubs privately organised by the medical practitioners themselves who employ collectors for the weekly subscription. The terms were the same as for the surrounding collieries—namely, 6*d.* per fortnight per family. As the County of Durham Medical Union had now been formed and was moving in the matter the Gateshead Medical Association also determined to raise the subscription to 9*d.* per fortnight. One member, however, who had just bought a practice which comprised such a club, said he did not feel justified in making this increase; and an exception was made on his behalf. This was perhaps a mistake, for it tended to create a bad precedent. Still a compromise was preferred to the losing of a member who after all was not underselling any of the other members, for he agreed not to take new subscribers at less than 9*d.* As these subscribers had no organisation of their own they could not resist. If they refused to pay the 9*d.* they could not find any other practitioner who would accept less, so the increase was easily obtained. For one out of the three or four Gateshead practitioners who attend to the neighbouring collieries that meant an increase of £150 a year to his income; and thus it became more and more evident that it was well worth while to unite and to organise the members of the profession.

Early in the year 1898 the Gateshead Medical Association resolved that it would have nothing to do with medical aid organised by financial insurance companies. All its members who had appointments in the service of these companies were called upon to give them up. This they did and without hesitation; but this did not entail any serious loss as fortunately these companies had only a feeble hold upon the town. At the same time, two or three quarrels broke out between some of the practitioners of Gateshead. The association at once took up these matters of dispute, argued out all the causes of disagreement, brought the disputants together, persuaded them to shake hands, and so put an end to all further wrangling. Then there were two cases in which the association was able to bring in the Medical Defence Union. One of the members was ill and he had reason to suspect that his locum-tenent, whom he had paid as a fully qualified assistant, was nevertheless not qualified. On leaving this assistant put up his plate in another part of the town. He was therefore invited to join the association, but refused. With the aid of the Medical Defence Union it was ultimately found that he had no qualification but was personating his brother who was qualified. A warrant was taken out for his arrest, but he escaped before it could be served on him. At about the same time two members of the Medical Association complained that a practitioner had been imported by some miners to attend to their families for 6*d.* instead of 9*d.* per fortnight and that he was employing an unqualified assistant. This assistant was living at a distance of a mile and a half from his employer and was doing full branch work, including midwifery. Again with the help of the Medical Defence Union, the practitioner was brought up before the General Medical Council and was severely reprimanded.

There is sometimes a feeling against the principle of preparing a black list of patients who do not pay their medical bills. But at Gateshead this list has proved a great success and there have been two editions. It is only sent to those who contribute to it and some of the practitioners do not take the trouble to look through their books and to send in names. Nevertheless, the amount of bad debts has been very much reduced by the black list, even though it be but an incomplete list.

On one or two occasions the Gateshead Medical Association has approached the corporation in relation to sanitary matters. Thus it memorialised the local authorities on the question of a public disinfector and urged that a disinfecting station should be established. This was ultimately done and the town council expressed its thanks to the Gateshead Medical Association for the advice that it had given on this subject. Such medical organisations might certainly greatly assist the medical officer of health in bringing pressure to bear so as to induce local authorities to take in hand necessary sanitary reforms. The Gateshead Medical Association also memorialised the General Medical Council so as to obtain clearer indications as to the position taken up by that authority in regard to unqualified assistants. The rule on this subject is open to several interpretations. The resolution of the General Medical Council, the Gateshead practitioners maintain, admits pupils, midwives, and dressers acting under supervision. The members of the Gateshead Medical Association showed by their discussions that they did not understand the practical bearings of this resolution, and the formal reply which they received from the General Medical Council did not help to enlighten them. They are all opposed to the legalising of the position of midwives and the granting of diplomas to opticians Then the Gateshead Medical Association managed to organise a meeting at which the Direct Representatives of the profession on the General Medical Council were present and discussed various subjects, but more especially the question of registering midwives. This meeting was the first occasion on which the three Direct Representatives for England met on the same platform The meeting took place before the Conference on Medical Organisation which met at Manchester in May, 1900 At this latter gathering the Gateshead Medical Association was well represented and introduced two of the principal resolutions, which pressed the need for concentration and urged that the constitution of the British Medical Association should be so reformed as to enable it to group together the medical organisations that deal with economical and ethical problems The Gateshead Medical Association also had occasion to make representations to the borough and county members of Parliament with regard to medical questions that were about to be discussed in the House of Commons. Finally, when the war broke out the members of the association offered their services gratuitously to the families of soldiers, sailors, or reservists who were in [illegible] e of the members went out to [illegible] isation was going on several practitioners came and established themselves at Gateshead Since 1896 there have been eight or nine new-comers. As soon as they arrive the secretary calls upon them, gives them a copy of the rules, explains the necessity of organisation, and relates all that has been accomplished and the advantages that have resulted therefrom. This has been done so well and so promptly that all the newly established practitioners have joined the Gateshead Medical Association, so that now the society has 45 members, and there is only the one practitioner who has been mentioned above who is not enrolled. The cordial relations prevailing among the members have been much encouraged by paying due attention to the social side of the organisation. Four annual dinners and two picnics have been held, and everything is done to promote conviviality and friendly social intercourse, thus seeking to obliterate the feelings of competition and rivalry which tend to disunite the members of the profession.

Apart from its own local work the Gateshead Medical Association has been very active in propagating its principles in the surrounding districts From Australia, America, and many British towns letters have been received asking for advice and for copies of the rules, which have been always readily forwarded Sometimes the president, sometimes the secretary, and, on other occasions, both president and secretary, have gone to inaugural meetings when, in some other locality, efforts were made to form a medical union. The practitioners at South Shields were the first to organise a society after that of Gateshead had been constituted, as has been already explained, and their earlier meetings were attended by Dr. Cox from Gateshead. The energetic secretary of the Gateshead Medical Association also helped to form the Newcastle Medical Ethical Society and the Mid-Tyne Medical Association at Wallsend Both of these societies have now been merged in the Northumberland and Newcastle Medical Association. Altogether the Gateshead Medical Association has shown that its members possess a broad grasp of the interests at stake and that they are not tied down by a narrow feeling of parochialism, but that they are ready to take their part in a general as well as in a purely local movement Thus the association not only participated in the Conference on Medical Organisation held at Manchester but the secretary, Dr. Cox, was a member of the International Congress of Deontology and Medical Ethics held at Paris last year. Undoubtedly the medical practitioners of Gateshead have set a good example. They have succeeded in securing practical unanimity, they have been prudent in their policy, and they have been eminently successful in their efforts.

Gateshead, March 25th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Ladies' Charity and Lying in Hospital: The School of Midwifery.

FROM the last annual report it appears that the number of cases admitted to the hospital during the year 1900 was 204 In eight of these the patients were single girls (first cases) admitted under the new rule During the year there were five deaths of mothers in the districts and one in the hospital, and of these six deaths only one was due to maternity. 24 students took their practical midwifery course with the charity during the year—an evidence that the arrangements made by the board of the hospital with University College to provide for this branch of the medical curriculum is meeting the end in view Formerly Liverpool students were compelled to take out their course of practical midwifery in Dublin 35 pupil midwives were trained in the School of Midwifery during the year and received certificates. 18 monthly nurses were trained by the matron in the hospital and received certificates of competency. The expenditure for the year exceeded the ordinary income by £694 Comparing the present position of the charity with that of 10 years ago it appeared that while great advances had been made in the treatment of the patients, both indoor and outdoor, in the training and efficiency of the staff of midwives, the provision of extra nursing for patients, and the benefits conferred on the community through the training of medical students, midwives, &c, the subscriptions and donations had decreased and the charity had now to face each year a serious deficit which had to be met by drawing upon invested funds The charity is one which ought to appeal strongly to the public; it has kept well abreast with the times and has done valuable work.

Liverpool and the Prevention of Tuberculosis.

At the second annual meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis held in London, the Earl of Derby, who was in the chair, alluded to the great progress which had been made in Liverpool in regard to the prevention of tuberculosis The corporation had within the last month adopted voluntary notification of phthisis and had also established depôts for the supply of sterilised milk Two sanatoria for open-air treatment were in course of erection and one, it was hoped, would be ready for patients in July. The council of the association drew attention to the satisfactory result of the three months' experiment recently made by the three Liverpool boards of guardians, which had adopted the plan of making it a condition of granting outdoor relief that the family should remove to more wholesome quarters and had adopted simple but efficient precautions for the prevention of infection To meet the cost of removal and also of more adequate nourishment for the patient they granted relief at a special scale.

The Liverpool Infirmary for Children.

At the annual meeting of the subscribers to the Infirmary for Children the chairman made the startling statement that the building was found to be insanitary and that there was no possibility of improving it so as to enable it to conform to modern ideas of hospital construction. One of the most serious drawbacks was the existence of the out-patient room in the same block as the wards which were in consequence exposed to the risk of infection in many ways. The committee therefore recommended the erection of a new building and the separation of the out patient department from the main building.

The New Botanical Laboratory for University College, Liverpool

The new botanical laboratory (the munificent gift of Mr. W. P. Hartley) in course of erection in Brownlow-street is rapidly approaching completion and will be formally inaugurated in October next The design is highly artistic and the new laboratory will be a handsome and imposing addition to the existing buildings in Brownlow-street, most of which are in connexion with University College.

The Sanitation of West Africa.

Mr Chamberlain received a deputation from the Chambers of Commerce of London, Liverpool, and Manchester and the Liverpool School of Tropical Medicine, at the Colonial Office, on the sanitation of West African coast towns. The Liverpool School of Tropical Medicine was represented by Mr. Alfred L. Jones (the chairman), Professor Rubert W. Boyce, Major Ronald Ross (late I.M.S.), Dr. H. E. Annett, and Dr. R. Fielding-Ould. The points submitted to Mr. Chamberlain included proposals that the governments of the various colonies on the west coast of Africa should be invited to prepare schemes, with estimates, for the complete organisation of sanitation in the coast ports in the vicinity of quarters permanently occupied by any considerable number of Europeans, especially with regard to (1) removal and disposal of refuse, (2) complete surface drainage of the soil and removal of bush and undergrowth, (3) removal of native huts where their presence is a menace to the health of Europeans, and (4) the institution of sanitary regulations for observance by the public within the areas indicated above; that at the same time a sanitary commissioner, or sanitary commissioners, should be appointed by the Colonial Office to visit repeatedly all the said colonies and to report to the Secretary of State the condition of sanitation in each colony and the steps being taken to improve it by the local authorities; that where new settlements are being planned quarters for Europeans shall be arranged as far as possible on the Indian cantonment model; and that special regulations shall be made to prevent the overcrowding of such cantonments by the general public. Mr. Chamberlain, in reply, said that the questions of water-supply, sewerage, and the other points to which his attention had been called were receiving the careful consideration of the Government. The question of cost was a serious one, to which they must give anxious consideration, unless they were to get into financial trouble. The points suggested meant no less than a gigantic system of sanitary inspection. If the Government sent out a purely expert scientific expedition they would be handing over practically the decision upon the cost, which was really a point for laymen. Mr. Chamberlain proposed, therefore, that the three chambers of commerce should each appoint one of their number to be a member of such a commission and that a representative from the Colonial Office should accompany it, perhaps as secretary; in addition to the three gentlemen they should also have a scientific expert whom they would nominate. If that view were accepted by the deputation he would refer to this small commission certain questions, the first and most important of all being the sanitation of the colonies and its cost.

March 28th.

WALES AND WESTERN COUNTIES.

(From our own Correspondents.)

Bristol Isolation Hospital.

The medical officer of health (Dr. D. S. Davies) has presented a report to the Bristol Health Committee urging the importance of providing additional accommodation at the isolation hospital at Ham Green. Although the population of Bristol is approaching 350,000 there is provision in the city hospitals for isolating only 100 adult patients, and there ought to be accommodation for at least 300. It is of interest in this connexion to record that until 1886 the Poor-law guardians of Bristol held themselves partially responsible for isolating infected persons and at that time there was accommodation for isolating at one time 120 persons, so that there is actually less accommodation at the present time than there was 15 years ago. The guardians now pay the city authorities £300 a year, in return for which all infected pauper patients are treated in the city isolation hospitals. Bristol cannot afford to be behind its neighbours in this respect. Cardiff since the end of last year has been very well equipped and has a much larger hospital than Bristol to serve a much smaller population.

Sanitation of the Welsh Wells.

The popularity of the Welsh wells is increasing year by year, but it will not continue to do so unless some of the sanitary authorities mend their ways. Dr. W. W. B. Fry, the medical officer of health of Builth, has frequently drawn the attention of the urban district council to the insufficiency of the sewerage of Llanwrtyd where the principal sewer discharges in the middle of the village into the river Irvan, and in the summer when the water is low there must of necessity be considerable nuisance caused. Now that septic tanks and bacterial contact-beds have passed the experimental stage there can be no longer any excuse for any sanitary authority allowing a stream to be polluted in the manner described by Dr. Fry in his last annual report, in which he says that it is scandalous that such a state of things should continue in a health-resort. The inhabitants of the village are to be congratulated upon having as their medical officer of health an official who is willing to speak thus forcibly.

The late Mr. R. Jeffreys Owen.

The death is announced of Mr. Richard Jeffreys Owen, M.R.C.S. Eng., L.R.C.P. Lond., of Llandovery, at the comparatively early age of 43 years. Early in the "eighties" Mr. Owen was house surgeon to the London Hospital and to the Poplar Hospital for Accidents. In 1899 he held the office of Mayor of Llandovery.

Publicans as Sanitary Inspectors.

The rural district council of Chard in Somerset recently elected a licensed victualler as one of their three sanitary inspectors, but the Local Government Board refused to sanction the appointment. In subsequent correspondence upon the matter the Board stated that it was their practice to object to licensed victuallers, house agents, and collectors of rents holding such appointments.

Gloucester General Infirmary and Eye Institution.

The annual meeting of the subscribers to this institution was held on March 28th, under the presidency of Colonel Curtis-Hayward. The medical report stated that during 1900 the in-patients numbered 1306, against 1329 in 1899. There were 8319 out-patients treated, compared with 8200 in the previous year. The financial statement showed that the ordinary expenditure amounted to £7210 and the income to £6956, leaving a deficit of £254.

Bristol Eye Hospital.

The annual meeting of the subscribers to the Bristol Eye Hospital was held on March 26th, under the presidency of the Lord Mayor. The ninetieth annual report, which was read by Mr. Richardson Cross, stated that during 1900 the out-patients numbered 4893, compared with 4975 in 1899. The in-patients numbered 256. The financial statement showed that the balance due to the treasurer had been reduced from £479 to £375. Towards the fund for the recent extension of the hospital £5016 had been received, but there still remained the sum of £1600 to be raised, for which sum the committee strongly appeal. Before the meeting the Duke of Beaufort formally opened the new extension of the hospital.

Bristol Royal Infirmary.

The annual meeting of the subscribers to this institution was held on March 26th, under the presidency of Sir Charles Cave. The medical report stated that 2986 in-patients had been admitted during 1900, compared with 3087 in 1899, and there were 38,671 out-patients treated, as against 39,883 in the previous year. 385 patients were sent to the Queen Victoria Jubilee Convalescent Home at Clifton. The financial statement showed that the total ordinary income amounted to £10,840, compared with £11,479 in 1899. The total ordinary expenditure was £14,925, against £14,393 in the preceding year. The chairman urged the necessity of increased financial help to the infirmary and added that although they had reduced the adverse balance from £13,000 to £7000 it had been done, unfortunately, by the sale of securities. Sir Charles Cave was re-elected president and treasurer for the ensuing year, a dual post which he has held for 21 years.

April 1st.

SCOTLAND.

(From our own Correspondents.)

Edinburgh Royal Infirmary.

At a meeting of the managers of Edinburgh Royal Infirmary held on March 25th Dr. R. Milne Murray and Dr. N. T. Brewis were elected to fill the respective posts of second and third gynæcologists to the institution. There were six candidates for the posts.

Small-pox in Glasgow.

The epidemic appears at last to be in a state of decline. The admissions during the last week show a considerable decrease compared with the last record. The authorities are taking a cheerful view of the future, and there is a general expectation that ere long the city will be reported free from the disease. Among the various criticisms which have been made it has been suggested that the admissions to hospital have included a not inconsiderable number of revaccinated patients. Possibly this rumour has induced the medical officer in his last report to introduce some recent facts bearing on this question. It appears that among the 316 patients in hospital on March 30th there were 39 patients who stated that they had been revaccinated at one time or another, and in 36 of these the date of the operation and of sickening from small-pox was readily ascertainable. A comparison of these dates shows that in every case the interval between revaccination and sickening falls short of the normal period of incubation, so that in every instance the disease had already been contracted before the operation was performed. In the three remaining cases the attack of small-pox followed the act of revaccination at 10, 21, and 28 years respectively. The notes on these three cases are as follows: 1. Female, aged 49 years, admitted March 1st; said to have been revaccinated in 1891. One mark only, however, is visible. The case is an exceedingly mild one. 2. Male, aged 44 years, admitted March 6th. He was revaccinated Feb. 23rd, eight days before sickening. He states that he was also revaccinated successfully in 1880. The attack is of so mild a character that considerable uncertainty at first existed as to the accuracy of the diagnosis. 3. Male, aged 36 years, admitted Feb. 23rd; said to have been revaccinated 28 years ago and two marks are visible. The attack resembles in mildness that of the previous patient. These facts and figures will do something to calm the public mind in face of the statements of the anti-vaccinationists. The latter are showing some tendency to increased activity and have secured Dr. W. R. Hadwen of Gloucester to conduct a lecturing campaign in the various wards of the city.

Glasgow University.

The city authorities are taking much interest in the academic events which are to mark the celebration in June next of the ninth jubilee of the University. At a recent meeting of the magistrates it was decided that a banquet should be given by the corporation to the various distinguished guests who will be present in the city in response to the invitation of the University Court and Senatus.—The examinations for degrees in medicine commence this week. For the first professional the entrants number 147; for the second professional, 137; and for the third professional, 74. These numbers include no less than 39 women candidates.

Microscopical Society of Glasgow.

The last meeting of this society was occupied by a lecture on "The Economic Importance of Bacteria," by Dr. R. M. Buchanan, bacteriologist to the city health department. The application of bacteria to various industries was shown by instances of their ferment-forming capacity, as in the manufacture of alcohol and the preparation of cheese. In agriculture the value of bacteria was illustrated by a description of the power which certain varieties possessed of fixing the free nitrogen of the air and presenting it to plants in a form suitable for their assimilative powers. The lecturer strongly insisted on the economic and national importance of the introduction into various agricultural processes of scientific knowledge and method. The lecture was well illustrated by numerous lantern slides, microscopic preparations, and culture tubes, and Dr. Buchanan was cordially thanked by the society.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Proposed Bacteriological Institute in Dublin.

THE movement in favour of the establishment of a bacteriological institute in Dublin continues to make progress. A conference is about to be held of delegates from many public bodies, colleges, and institutions. At the quarterly meeting of the Dublin Corporation, which took place on April 1st, Sir Thomas Pile moved the adoption of a report of the Public Health Committee recommending the establishment in Dublin of a bacteriological institute. The committee were of opinion that such an institute was much required, and they thought that it should be a national one supported by all the public institutions and sanitary authorities in the country. They understood that it was proposed to establish in Dublin a pathological institute in connexion with all the lunatic asylums of Ireland. As the work of such an institute would be mainly bacteriological the committee thought that one institute would suffice, and the corporation, as the principal supporters of, the largest lunatic asylum in Dublin, must naturally feel interested in all matters pertaining to the pathology of the insane. The committee suggested that the council should express approbation of the proposal to establish a bacteriological institute and should undertake to afford some pecuniary help in establishing and maintaining it. The motion was passed unanimously.

Death of Dr. Arthur K. F. McCutcheon.

Dr. Arthur K. F. McCutcheon died at his residence, 3, Rutland-square, Dublin, on March 27th. He was a graduate in medicine of the University of Dublin, and was elected a Fellow of the Royal College of Physicians of Ireland in 1895 He held the position of physician to the Whitworth Hospital, Drumcondra. His funeral, which took place on March 30th, was attended by the President and Council of the Royal College of Physicians of Ireland. A large and representative gathering of the members of the medical profession was present. The untimely death of Dr. McCutcheon at the comparatively early age of 43 years has caused much grief among his friends.

Richmond, Whitworth, and Hardwicke Hospitals, Dublin.

Mr. Robert D. Joyce has been appointed ophthalmic surgeon to the House of Industry Hospitals, in the room of Dr. Archibald H. Jacob, deceased.

The British Association.

At a meeting held in Belfast on March 29th, the Lord Mayor presiding, a local general committee was appointed to make provision for the reception of the British Association in 1902, in accordance with an invitation accepted from Belfast for that year. A treasurer and three secretaries were also elected.

Belfast Ophthalmic Institution.

At the annual meeting of the friends of this excellent institution, held in Belfast on March 29th, it was reported that 1267 eye cases, 298 ear cases, and 259 throat and nose cases were treated as extern patients. There were also 104 intern patients. Alterations are about to be made which will improve the extern rooms and will provide a new operating theatre. Dr. Victor Fielden has been appointed anæsthetist to the hospital. The High Sheriff of Belfast, who presided, warmly congratulated the senior surgeon (Dr. Walton Browne) on his recovery after his late illness.

Irish University Education.

A series of important resolutions on this question have just been passed by the Ulster Liberal Unionist Association. They approve of the appointment of the Royal Commission to inquire into the circumstances of higher education in Ireland. They urge that the Commission should be composed of men of universally acknowledged eminence in educational and public affairs and who are superior to sectarian and political partisanship. If this is not done the conclusions of the Commission will fail to command respect in any quarter and will *simply* result in intensifying the existing confusion in Irish university conditions. They also recommend that in the interests of commercial, agricultural, and manufacturing industry in Ireland, commercial education should be included as a branch of university work, and that a suitable connexion should be formed between the organised courses of agricultural and technical colleges and the university curriculum in such a manner that work of a scientific character done by students at such colleges might become an avenue to a university degree. They suggest that the proposed Royal Commission should be instructed to take evidence and to report upon the relations existing between the universities and commercial, agricultural, and technical education in Great Britain and in foreign countries, and to recommend in what way such education may be effectively brought within the sphere of university influence in Ireland.

Food Unfit for Human Consumption: Interesting Action at Cork Assizes.

Mrs. Blessing Walis, widow of a solicitor, brought an action before the Lord Chief Justice at the Cork Spring Assizes against Mr. Thomas Russell, fish merchant, for breach of warranty of certain goods—namely, two crabs—and for supplying goods unfit for human food, whereby the plaintiff became dangerously ill. Damages were laid at £1000.

There was a formidable array of counsel for both sides and the case excited very considerable interest. According to the evidence Mrs. Wallis sent her grand-daughter, a Miss Donovan, to Mr. Russell's establishment for two crabs, and one of Mr. Russell's assistants in the course of the sale described the crabs as being sound and good in reply to a question by Miss Donovan. The crabs had been already boiled on Mr. Russell's premises. Miss Donovan took them home and without further dressing she and her grandmother partook of some of the claws at tea. On opening the shells of the bodies of the crabs they were found to contain a brownish fluid. On being removed downstairs the servant ate portions of the claws, but on noticing the contents of the shells threw what remained of the crabs into the ash-pit. After a few hours had elapsed Mrs. Wallis, Miss Donovan, and the servant became very ill and the symptoms of the illness were very similar. Mrs. Wallis suffered from diarrhœa, vomiting, and collapse and was for some time unconscious. Another grand-daughter of Mrs. Wallis hearing of her grandmother's illness arrived on the following morning and on going out to the yard where the remnants of the crabs lay she noticed a distinctly bad odour when some yards away from the crabs. The medical evidence showed that the three patients had been suffering from irritant poisoning. For the defence the man who had sold the crabs to Mr. Russell gave evidence and Mr. Russell was also examined. He deposed that he exercised every care in the selection of the crabs and that he had made inquiries with regard to several others of his customers who had purchased crabs out of the same consignment and that none of them had suffered. The hearing lasted for part of two days and it resulted in a verdict for the plaintiff, the damages being laid at £150. It is stated that an appeal will be lodged by the defendant.

April 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Respiratory Chemistry of Phthisis.

AT the meeting of the Academy of Medicine held on March 19th M. Robin communicated the results of some researches which he had made upon 392 patients with regard to constitutional conditions (*terrain*) predisposing to phthisis. One well-known characteristic of phthisical patients is a loss of organic mineral matters. But there is another which is quite opposed to the ordinarily expressed ideas. It is generally thought that both respiratory changes and hæmatopoiesis are much diminished in phthisis. On the contrary, respiratory exchange is much increased in this disease, and of 162 cases examined this peculiarity was found in all but eight. The respiratory chemistry of phthisis is something quite peculiar. A healthy man consumes per kilogramme of body-weight per minute 107 cubic centimetres of air. For phthisical patients the figures are as follows: men, 192 cubic centimetres and women 225 cubic centimetres. A normal man consumes 5·13 cubic centimetres of oxygen, a phthisical man 8·72 cubic centimetres, and a phthisical woman 10·29 cubic centimetres. A healthy man expires 4·17 of carbon dioxide per kilogramme per minute, a phthisical man expires 8 85 cubic centimetres, and a phthisical woman 7·5 cubic centimetres. A healthy man absorbs 0·85 cubic centimetre of oxygen per kilogramme per minute, a phthisical man 1·87 cubic centimetres, and a phthisical woman 2·5 cubic centimetres. This exaggeration of respiratory exchange exists in a less degree in fibrous tuberculosis. It has been observed in the very earliest stages of the disease long before any auscultatory signs are perceptible. It exists also in the latest stages. It can be definitely stated therefore that in 92 per cent. of phthisical patients the respiratory exchanges are much increased in every stage of the malady. These results hold good in cases of tuberculosis of the bones, but they are not found in tuberculous peritonitis or meningitis or in lupus. In 40 cases of various morbid types the conditions noted differed. In typhoid fever exchange was lessened. In influenza it was slightly increased. Shortly, although in some diseases the respiratory exchange was slightly increased, in no one was the increase comparable with that existing in phthisis. Therefore, in doubtful cases the study of the respiratory chemistry will enable the physician to make a diagnosis at a very early date and in various cases M. Robin and M. Binet have been able to diagnose a tuberculous predisposition (*terrain*). In sundry cases when they noted exaggerated respiratory exchange the patients were attacked by tuberculosis and died. On the contrary, a patient in whom numerous bacilli were found, but whose respiratory exchange was unaltered, recovered. This method of examination may serve to separate patients with a tuberculous history into those who are predisposed to the disease and those who are free from all taint. *Finally, it may be considered that examination of* the respiratory exchange offers a method of the very first rank for making an early diagnosis in cases of tuberculosis.

Helminthiasis in China.

At a meeting of the Academy of Medicine held on March 25th M. Laveran read some notes by Dr. Matignon on helminthiasis in China and its apparent influence in the production of appendicitis. Dr. Matignon remarked on the extreme frequency of intestinal worms in China. Among adult Chinese they were found to exist in 75 out of 100 cases examined, and in Chinese children they were found in 98 out of 100 cases. Among adult Europeans they were found in 25 per cent. of the cases examined. Despite these figures Dr. Matignon during a period of four and a half years saw only one case of appendicitis in a Chinese and not more among 150 Europeans who came under his care. In one young girl and two missionaries he noticed signs resembling those of appendicular colic which were, however, due to tænia. In Northern China appendicitis is completely unknown. The populace is almost completely vegetarian. In Peking and its suburbs the Chinese eat only a small quantity of meat, and that of duck, chicken, mutton, or pork. Their chief articles of food consist of millet, rice, maize, potatoes, and turnips. They also eat unleavened cakes of maize or wheaten flour, cooked by steam. It is very likely due to this *régime* that appendicitis is so rare in China and it may also be the cause why the digestive functions among the Chinese are so regularly performed. Constipation among them is extremely rare.

April 2nd.

Obituary.

JOSEPH FODOR, M.D.,

OF BUDAPEST.

WE sympathise with our Hungarian brethren on the occasion of the great loss they have sustained by the death of Dr. Joseph Fodor, Professor of Hygiene at the University of Budapest. The members and delegates who took part in the Eighth International Congress of Hygiene and Demography will remember the courteous manner in which Professor Fodor received them as President of the Organising Committee, and to him was due in no small degree the undoubted success of the Congress at Budapest.

Joseph Fodor was born in 1843 of noble parents at Lakocsa, in the county of Somogy in Hungary. He studied medicine at Budapest and Vienna and in 1865 graduated as Doctor of Medicine. The next year he filled the post of assistant to Dr. Rupp, Professor of Medical Jurisprudence, and on the recommendation of the late Dr. Markusovszky obtained in 1870 a travelling scholarship from his Government, to become a pupil of Dr. Pettenkofer at Munich and later of Baron Liebig. He worked in the laboratories of Recklinghausen and Flalger in Würzburg and then visited other parts of Germany, Holland, Belgium, and England. In 1870 he returned home and was appointed to the chair of Medical Jurisprudence in the University of Kolosvár in Transylvania; four years later he become professor of hygiene at Budapest. For 28 years he devoted his energies to studies in connexion with sanitation. His work on "Hygienic Investigation of Air, Soil, and Water" was awarded the prize of 200 ducats by the Academy of Sciences of Hungary and was translated into German. He introduced Pettenkofer's principles of hygiene in Hungary and created a school and literature in his country on sound principles of sanitation, the effects of which are now generally felt through the successful efforts of numerous pupils; one of the most distinguished among them was the late Dr. Eugen Farkas, well known to many in England. Thanks to the coöperation of the late Dr. Markusovszky and the patronage of the Minister of State, M. Trefort, sanitation is now placed on a sound basis in Hungary. Whilst joint editor of the medical journal, *Orvosi Hetilap*, Dr. Fodor successfully propounded a scheme that not medical students only, but other undergraduates of the University—namely, law students, engineers, and chemists—should attend a course on the principles of general sanitation. To popularise his scheme he helped to establish a "Society of Sanitation," first mooted by Dr. Markusovszky, and through its organ, *Egészég* (Health), rendered most useful service to the public at large.

Professor Fodor also did good work as member of the Academy of Sciences, holding the position of president of the natural history section and acting as editor of its journal. We find him throughout his life a conscientious labourer in the domain of science: his colleagues knew his worth and accorded to him their appreciation. At the university he attained the highest positions, first as dean of the faculty and finally as rector magnificus. Honours at home and from abroad were heaped upon him; he was nominated ministerial councillor and was decorated by the Sovereign with the Order of the Iron Crown, and he received—and of all his academical distinctions this was the one which he valued most—the LL.D. of the University of Cambridge. In private life Dr. Fodor possessed qualities which endeared him to others—modesty, unselfishness, devotion to friends, and readiness to oblige all who came in contact with him. The tenour of his life, though generally happy, was disturbed by domestic sorrow; he lost his wife after much and prolonged suffering, and also his daughter Madame Gerlóczy; while other private troubles also told considerably upon a not over-strong and highly sensitive constitution.

At the beginning of the present year Professor Fodor suffered from a severe attack of influenza. In due course he was able to go about, but strength was slow in returning. In the first days of March he was again confined to his bed, during which time he had the misfortune to sustain an injury to the left leg which necessitated the removal of the limb at the upper third of the thigh. The stump healed well, but he did not recover entirely from the double shock of injury and amputation. On March 19th death put an end to his sufferings at the comparatively early age of 58 years. He was accorded a public funeral, starting from the palace of the Institute of Public Hygiene; the presence of Ministers of the Crown, of members of the aristocracy and of both Houses of Parliament, of deputations from various public bodies, and of a large concourse of mourners generally, testified to the universal esteem in which the deceased was held. Many friends and patients will feel his loss, but none more than his devoted pupils, who, 100 in number, bearing torches, ranged themselves round the coffin of their beloved master on the journey to his last resting-place.

WILLIAM RICHARD ROGERS, M.D. HEIDL., M.R.C.P. LOND.

DR. WILLIAM RICHARD ROGERS, who recently died at his residence, 26 Upper Baker-street, N.W., was born in 1817 and received his education at University College, London. In early life he travelled a good deal on the continent, for two years "walking the hospitals" in France and Italy, and also visited Tunis. He subsequently came to London and practised for many years in Berners street. He graduated M.D. and D.S. of the University of Heidelberg in 1838 and became a Member of the Royal College of Physicians of London in 1859. He served as physician to the Samaritan Free Hospital for 24 years, being made consulting physician in 1882 and vice-president in 1899. He was for a time consulting surgeon to the Grosvenor Hospital for Women and Children, Vincent-square, Westminster, S.W., and senior physician to the Farringdon General Dispensary. He was the author of several papers on Inflammation and Obstruction of the Cæcum, Inversion of the Uterus, and Ruptured Perineum. Late in life he met some misfortunes, especially through the failure of an insurance office, and his health broke down so that he was obliged to give up practice. He was married to a very talented lady, an artist of some distinction, by whom he had several daughters and two sons, the elder of whom is surgeon in His Majesty's navy. Dr. Rogers was of a rather retiring disposition, but much beloved by his patients and fellow-practitioners—a man without an enemy.

Medical News.

VICTORIA UNIVERSITY.—A degree ceremony was held at the Owens College on March 29th when the following candidates were presented. The candidates from Owens College were presented by Professor Young and those from University and Yorkshire Colleges by Professor Chadwick. The degrees were conferred by the Vice-Chancellor (Principal A. Hopkinson of Owens College). Professor Sinclair, Professor Wild, and Mr. Edward Fiddes were also present.

BACHELOR OF MEDICINE AND OF SURGERY.

John Thomas Bailey, Owens; James William Henry Brown, Yorkshire; Charles William Budden and John Scott Byrne, University; Andrew Campbell Clarke, Charles Hollows Dawson, Theodore Llewellyn Fennell, and Robert Francis Ferris, Owens; Robert Thomas Forster, Yorkshire; James Percy Good, Reginald Gordon, Frederick George Hack, Herbert Shaw Lister, and James McIlraith, Owens; Arthur Francis Martin, Yorkshire; Albert Ramsbottom, Claude William Scott Saberton, Harry Slater, and Thomas Tierney, Owens; Roger Durant Willcocks, University; and Henry Merrill Williamson, Owens.

In the Faculty of Medicine the following candidates have passed in the subjects indicated:—

FINAL EXAMINATION.

Part I.—[illegible] Bolton, Yorksh[illegible] W. H. Canter, [illegible] Yorkshire; [illegible]hnson, C. O. J[illegible]wens; W. L. M[illegible]kshire; E. E. Roberts, University, Frank Sugden, Yorkshire; and S. W. Swindells, Owens.

SECOND EXAMINATION.

A. Anatomy and Physiology.—John Battersby, A. N. Benson, and Alexander Boothroyd, Owens, Alan Boyle and W. E. Brierley, Yorkshire; Howard Buck and Laurence Clay, Owens; Richard Coates, Yorkshire; Thomas Coogan, Owens; Edward Cundall and A. M. Deane, Yorkshire, Douglas Elder, University; J. L. Falconer, Owens; Ernest Gibson, University; Tom Glover, J. W. Hartley, and H. D Haworth, Owens; S. L. Heald, Yorkshire; J. P. Henderson, Arthur Hendry, and W. E. Hewitt, University; Hubert Hodge, Owens, C. A. Hughes, A. D. Hunt, and H. R. Hurter, University, Hamilton Irving and J. M. H. Jones, Owens; G. H. Joseph, George Laurence, and J. T. Lloyd, University; T. W. Lonsdale, Owens; H J. Macvean, Yorkshire; J. de V. Mather and H. J. Moon, Owens, D. J. Mulholland, University; G. G. Parkin, F. G. Pell-Ilderton, R. N. Porter, W. B. Ramsden, and Frank Robinson, Owens; F. H. Salisbury, University; J. L. Schilling and W. G. Scott, Yorkshire; Harold Simms, R. T. Slinger, J. C. Smyth, and R. H. Swindells, Owens; A. B Sykes, University; F. P. S. Thomas, Owens; H. G. Thompson, University; Leonard Thorp, Owens; M. G L. Walker, Yorkshire; and Douglas Wardleworth, S H. West, and E. M. Wilkins, Owens

B. [illegible] N[illegible] J[illegible] Owens; Lancelot Hutchinson, University; Walter Longley, Yorkshire; Hugh McManus and D J. Mulholland, University; C. S. O'Neill, Owens; E. W. Reed, Yorkshire; S. H. Ryan and W. F. Shaw, Owens; I. C. Thorburn, University; and W. F. J. Whitley, Yorkshire.

The University Scholarship was gained by H. D. Haworth (Owens); *proxime accessit*, Alan Boyle (Yorkshire).

THE PREVENTION OF TUBERCULOSIS.—A public meeting was held at Devizes on March 27th, under the presidency of the rector (Rev. J. Watson), in support of the scheme for erecting a sanatorium for consumptives at Winsley, near Bradford-on-Avon. Addresses were delivered by Dr. P. Watson Williams, Dr. L. A. Weatherly, Mr. G. S. A. Waylen, and others, and it was decided to form a local committee consisting of Mr. E. Colston, M.P., the Mayor, the members of the medical profession in Devizes, and others, to take steps for raising the necessary funds.

OVERHEAD DANGERS IN MANCHESTER.—Manchester is exercised in mind on the subject of overhead wires, and a meeting of the special joint committee appointed by the Telephones, Paving, and Tramways Committees of the corporation was held on March 15th to consider the question. It appears that there are 7798 wires over existing lines of tramways and 3781 crossing intended routes of tramways. There are 60 miles of telephone pipes under the streets. They are in cables running from the telephone exchange to buildings in each local area in which subscribers are situate. Each cable is opened out on the top of a building in a local area into short overhead wires connected to the nearest chimneys or corners of buildings in which there are subscribers. The overhead cables are insulated and contain about 104 wires each. The postal telegraph wires are apparently not insulated, as in the city surveyor's report it is said that the danger from these when crossing over tramway routes "would be reduced by enclosing them in insulated cables." The result of the discussion was that the town clerk was directed to prepare a report showing the legal status of the corporation as regards overhead wires. The sword of Damocles was nothing compared to our modern improvements on that weapon, as witness the Liverpool tragedy.

Fees of Public Vaccinators.—At the meeting of the Chippenham Board of Guardians held on March 18th a letter was received from Mr. J. P. Martin of Box, declining the appointment of public vaccinator for that parish at the fee of 5*s*. per case. The guardians decided to ask Mr. Martin what remuneration he would consider to be reasonable.

Western Counties Veterinary Association.—The annual meeting of this association was held at Exeter on March 28th under the presidency of Mr. T. G. Bond. Mr. John Dunstan read an interesting paper on Bacteriology in its relation to Veterinary Science and a discussion followed. Mr. R. Penhale was elected president for the ensuing year.

Superannuation Allowance.—Mr. B. Simmons, formerly medical officer of the Wotton-under-Edge (Gloucestershire) district of the Dursley Union, has been granted a superannuation allowance of £56 per annum.

Vaccination Fees.—At the last meeting of the Liskeard Board of Guardians it was reported that the vaccination fees amounted to £42 in 1899 and to £183 in 1900.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Nursing in Irish Poor-law Institutions.

When the House of Lords meets after the Easter Vacation, Lord Monteagle of Brandon will raise the question of nursing in workhouse infirmaries and fever hospitals in Ireland and will move for a return on the subject.

Hours of Labour in Shops.

The Committee of the House of Lords on the hours of labour in shops are accumulating a large body of evidence in favour of earlier closing and Lord Avebury's Bill. Witness after witness has stated that no more is to be hoped for from voluntary effort and that legislation is absolutely essential in existing circumstances. At a recent meeting of the Committee a letter was read from Professor J. G. McKendrick of Glasgow in which he said that he has no doubt whatever that the present long hours and confinement of shop assistants are injurious to health, and also one from Dr. D. Yellowlees of the same city saying that he was quite sure that the unreasonably long hours and close confinement of shop assistants are a great evil and are often not only a great hardship but very injurious physically, mentally, and morally.

HOUSE OF COMMONS.

Thursday, March 28th.

The London Water Question.

Dr. Macnamara asked the President of the Local Government Board whether he would place the text of his proposals respecting London water before the House before the close of the present session so that they might be duly considered by the people of London and the extra municipal areas affected during the Parliamentary recess.—Mr. Long: No, sir; I am unable to assent to the suggestion.

Factory and Workshop Legislation.

At this sitting Mr. Ritchie introduced two Bills, one to amend and the other to consolidate the Factory and Workshops Acts. In explaining the former he said on the subject of regulations for dangerous trades that under the present law there might be many arbitrations with respect to the orders of the Secretary of State. That was proposed to be abolished by the Bill of his predecessor (Sir Matthew White Ridley) last session, who proposed that the regulations should be referred to a referee, who should give his decision, which would be binding upon the Secretary of State in the sense that he must either comply with the decision or abandon the regulations altogether and substitute new ones. For his (Mr. Ritchie's) part he thought that there were strong objections to this principle of arbitration. He did not think it was right that the responsibility should be taken off the shoulders of the Secretary of State and put upon those of an irresponsible outsider. He proposed, therefore, that the Secretary of State should be responsible for making the rules relating to dangerous trades, subject to two conditions—first, that he should be bound to make the fullest inquiries and to receive evidence in public; and, secondly, that the rules should lie on the table of both Houses of Parliament for six weeks before they took effect. There was another important modification. The present state of the law relating to laundries was unsatisfactory and confused. He proposed to apply to laundries the provisions of the Factory Acts, preserving the existing distribution of hours. There was another important alteration with regard to laundries. Last year's Bill excepted the inmates of any institution conducted in good faith for charitable purposes. This exception, in his view, was indefensible. These laundries ought not to be worked upon conditions other than those imposed upon ordinary laundries, with which they, in many cases, competed If they were not so worked they had nothing to fear from the application of the Act to them, and, accordingly, he proposed to bring them within the Act. He proposed to insert special provisions to meet the objections which had been expressed to the inclusion of religious institutions.—Both Bills were read a first time.

Friday, March 29th.

Plague at Cape Town.

Sir Walter Foster asked the Secretary of State for War whether, in view of the increase of plague at Cape Town and the danger of importing the disease into this country, he would direct that all military invalids and soldiers arriving at English ports in ships on which any case of plague had occurred should be isolated and kept under observation for a sufficient period before being allowed to go to their homes or to military camps —Mr. Brodrick replied that instructions to this effect were issued on March 22nd to all concerned.

Monday, April 1st.

Army Medical Officers and the Age of Recruits.

Mr. Pirie asked the Secretary of State for War, with reference to ascertaining the correct ages of recruits and the evils of the existing system, if he would state in what respect the oath of allegiance taken by the recruit on attestation was an oath as to correctness of his age, and if he would consider the advisability of altering the oath so as to make it refer more directly to this point and at the same time to include among punishable offences any false statement of age on his part, if he could state why more care was not exercised by the army medical officers in their duty in this respect, and whether in future neglect as to this on their part would be dealt with more severely; and who was the medical officer responsible for the enlisting as a full-grown private soldier of George H. Over, who was only 14 years old, and whether the officer had been reprimanded.—Lord Stanley replied: The oath of allegiance has nothing whatever to do with the matter. On attestation the soldier signs his name to a declaration that his answers to various questions are true, amongst which is a question as to age. I am advised that a conviction for making a false statement as to age cannot be obtained. There is no reason to suppose that medical officers are careless on the point of age and in this particular case the officer does not appear to have been to blame as the recruit was well grown.

Standards for Milk and Cream.

Mr. Strachey asked the First Lord of the Treasury whether he could say what opportunity there would be for the House to consider the report and recommendations of the Departmental Committee of the Board of Agriculture in reference to fixing standards for milk, cream, and separated milk before they were adopted —Mr. Balfour replied: I understand that the departmental committee to which the hon. member refers reported about a fortnight ago and that my right hon. friend at the head of the Board of Agriculture (Mr. Hanbury) intends to give a reasonable time for representations to be made by those interested as to the mode in which the report should be dealt with. I do not think that a specific opportunity could or should be given to the House for dealing with a matter within the discretion of the department and vested in it by statute.

Isolation Hospitals Bill.

This Bill to improve the position of county councils with regard to the provision of isolation hospitals was read a second time and referred to the Standing Committee on Law. Mr. C. Hobhouse took exception to some of the clauses and Mr. Walter Long, President of the Local Government Board, explained to him that the Bill had been framed by the County Councils Association and all that had been done by his department was to make certain slight alterations which had received the approval of the association. The sole object of the Bill, Mr. Long added, was to enable county councils to do work in the direction of providing isolation hospitals which they could not do in the existing state of the law.—Sir Walter Foster expressed his approval of the measure.

Cremation Bill.

Sir Walter Foster moved the second reading of the Cremation Bill, a measure which has already passed through all its stages in the House of Lords. He explained that it was permissive in its character and gave power to local authorities to erect crematoria for the use of the locality, subject to the approval of the Local Government Board, and under regulations which had been sanctioned by the Home Office.—Mr. Ritchie said that the Home Office raised no objection to the general principle of the Bill. No doubt at one time cremation was regarded with some suspicion, but public opinion on the subject had considerably advanced of late years. When the Bill reached the Committee stage it would be their business to see that proper safeguards were introduced, and with that reservation he offered no opposition to the measure.

The Bill was read a second time and referred to the Standing Committee on Law.

ROYAL COMMISSION ON ARSENICAL POISONING.

Tuesday, March 26th.

The Commission held another meeting to-day in the Town Hall of Manchester, the members present being Sir William S. Church (who presided), Professor Thorpe, and Dr. B. A. Whitelegge.

Dr. J. Dixon Mann, Professor of Forensic Medicine in Owens College, gave evidence as to cases of arsenical poisoning that had come under his observation in hospital and private practice. He explained that he had examined the hair of patients, especially women, and found in it arsenic in amounts varying from half a gramme to two grammes. In one or two cases he found arsenic in the hair and nails without any other symptoms of arsenical poisoning. In many cases h [illegible] indeed, [illegible] patient [illegible] of arse [illegible] tinguisl [illegible] latterly disposed to think that it was possible that there had been small quantities of arsenic in beer, which would account for the widespread neuritis which had been fairly common in hospital practice prior to this epidemic. He had, however, known cases of neuritis in which the patients had taken spirits exclusively. *His recent investigations* had led to the conclusion that arsenic remained much longer in the tissues than he had before thought possible. In one case a woman was in the hospital for 62 days and yet had arsenic present in the tissues. The fact that women had suffered so much more than men was probably due to the want of activity in women. It was a question of elimination and many of these women were chronic alcoholics who did not move about much and whose tissues were not, so to speak, in activity. From the amount of arsenic he had found in cases he would say that there was more arsenic in the beer than had been accounted for by analysis. To make an absolutely exact analysis of beer was a very laborious process and on the whole he thought the amount of arsenic had been under- rather than over-estimated. He could not accept the statement that one- [illegible] would be innocuous.

[illegible] ng Company, Limited, [illegible] ard mainly to the use [illegible] brewers to free their plant from traces of arsenic.

Mr. C. ESTCOURT, analyst to the corporation of Manchester, submitted the results of analyses of beer. He advocated a uniform method of analysis and a standard test for beer, giving as a reason the discrepancies which had appeared in connexion with the present inquiry. He stated that three public analysts examined portions of the same beer and one obtained one twelfth, another one-tenth, and the third one-twenty-fifth of a grain of arsenic per gallon of beer. There were many difficulties under the Public Health Acts in dealing with [illegible] cases postponed for several weeks.

[illegible] to the Lancashire County [illegible] between Nov. 27th and [illegible] on of arsenicated beer [illegible] bottles, and 12,395 half- [illegible] destroyed privately by [illegible] nce Jan. 14th no case of [illegible] fficiently serious to give [illegible] to the end of February [illegible] the matter was that it [illegible] an amount of arsenic [illegible] If the presence of arser [illegible] saw no reason why absol [illegible] position was already adm [illegible] hesitate freely to advertise [illegible] received from medical office [illegible] 138 districts within the administrative county cases of arsenical poisoning had been observed, and information was given of 863 cases and 12 deaths, including two certified by the coroner after inquest. These figures did not, in his opinion, represent the total number of cases of poisoning in the county.

Mr. FRANK SCUDDER, chief assistant to Sir Henry Roscoe, gave the Commission analytical results.

The Commission then adjourned.

FRIDAY, MARCH 29TH.

[illegible] the Town Hall, Manchester, the [illegible] (chairman), Sir WILLIAM S. [illegible]HITELEGGE.

[illegible] e Manchester Royal Infirmary, [illegible] he had made a special study of neuritis and no doubt some of the cases of peripheral neuritis he had formerly seen might have been due to arsenical poisoning. Possibly a [illegible] a grain or over the whole [illegible] rugs Act to stop the sale [illegible] ell expressed the opinion [illegible] ng beer for arsenic.

[illegible] nist, West Gorton, said [illegible] but probably not more [illegible] for such a contamination. [illegible] products used in large quantity and he therefore concluded that they had most probably been the means of introducing the arsenic into the beer and this was found to be the case on testing the sugars. He found the sulphuric acid which was tested not only to contain a large amount of arsenic, but actually to be saturated with the poison. A very small amount of arsenic was found to be present in most of the other brewing materials and it was therefore evident that the arsenical glucose was the chief cause of the outbreak of disease under investigation.

Mr. HENRY WELD-BLUNDELL, chairman of the Cornbrook Brewery Company, and Mr. G. E. COWELL, managing director of Wilson's Brewery, Newton Heath, also gave evidence, and thereafter the Commission adjourned.

SATURDAY, MARCH 30TH.

The Commission held another meeting to-day in the Town Hall, Manchester, with Lord KELVIN in the chair.

Mr. SIGMUND STEIN, consulting chemist, Liverpool, gave the opinion that sulphuric acid should always be a purified acid from whatever source it came and said that it was necessary that there should [illegible] Speaking from long experience of the manufacture of glucose he said that the presence of arsenic in it was the exception and not the rule, and he insisted that if a penalty were imposed by law in all cases where arsenic was *found in glucose manufacturers would see that it* was not present.

Mr. H. SPENCER, of the Inland Revenue Department, in the course of examination said that priming was supposed to add to the briskness of the beer and increase its refreshing qualities. The officers of the department, like everybody else, were very much astonished when they learned that arsenic was being found in beer. If they knew that a brewer was adding something objectionable to his beer it would be the duty of the officers of the department to take cognisance of the fact, report the matter, and await instructions. The brewers had sought to get a return of the duty paid on the tainted beer, and while some cases were pending, others had been settled. The officers of the department had no knowledge whatever of the beer in the cellars of publicans, but the whole of the beer which was supposed to be contaminated and which the brewers presented to the officers of the department *to take an account of* was destroyed under [illegible] were not employed [illegible] purposes and to [illegible] beer was in the brewery.

The Commission then adjourned.

Appointments.

Successful applicants for [illegible] Institutions, and others possessing [illegible] umn, are invited to forward it [illegible] the Sub-Editor, not later than [illegible] of each week, for publication in the next number.

ALLINSON, H. C, M.R C.S., has been appointed Medical Officer of Health, Borough of King's Lynn.

ANDREWS, W. H., L.R.C.P., L.R.C S. Edin., L.F.P.S. Glasg., has been re-appointed District Medical Officer by the Kingsbridge (Devon) Board of Guardians.

BERGMAN, L. H. (in practice before 1878), has been appointed Dentist at the Workhouse Incorporation, Kingston-upon-Hull.

BEVILLE, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer, the Workhouse, Uxbridge Union, vice L. J. Minter, resigned.

BROADBENT, F., L.R C.P. Edin., M.R.C.S., *has been appointed District* Medical Officer, Lincoln Union

BURGESS, ARTHUR H., M.B, Ch.B., M.Sc., F.R.C.S. Eng., has been appointed Visiting Surgeon to the Manchester Union Hospital, Crumpsall.

[illegible] appointed Surgeon to H.M. Prison, [illegible]

CROSS, R. G., L.R.C.P. Lond., M.R.C S., D P.H., has been appointed District and Workhouse Medical Officer, Petersfield Union, vice C. S. Ticehurst, resigned.

DISMOOR, H. B, L.R.C P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse, and Assistant Medical Superintendent to the Infirmary, Lewisham Union.

EADON, W. F. BAILEY, L.R.C.P., L.R.C.S, L.M. Edin., has been re-appointed Medical Officer for the Second District of the Chipping Sodbury (Gloucestershire) Union.

FORREST, J. G. S., L.R.C.P. Lond., M.R.C.S, has been appointed District Medical Officer to the Corporation of Bury St. Edmunds, vice A. H. Gibbon, resigned

GIMSON, K. C., M.B., B C. Camb., has been appointed Medical Officer to the Bridge School at Witham, Metropolitan Asylum District.

GLEGG, WILFRID, M.D., M.R.C P. Edin, has been appointed Senior Resident Medical Officer to the Throat Hospital, Golden square, London, W.

GRIFFITHS, A. D, M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Cottage Homes, Isle of Thanet Union

GRÜNBAUM, O. F. F., M.A., B C. Cantab., D Sc. Lond., has been appointed Clinical Pathologist at King's College Hospital, London.

HARRIS, JOHN HENRY, M.R.C S, L.S.A., D P.H. Camb., has been re-appointed District Medical Officer by the Kingsbridge (Devon) Board of Guardians.

HILL, PHILIP EDWARD, M.R.C S., L.S A. Lond., has been appointed Medical Officer of Health for the Crickhowell Combined Districts.

JAMES, W. T., M.B., Ch.B. Edin., has been appointed Assistant Medical Officer to the Infirmary for Children, Myrtle-street, Liverpool.

LLOYD, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Second Assistant Medical Officer to the Infirmary, Lewisham Union, vice A. Carter, resigned.

LORIMER, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Farnham Union, vice H. Sloman, resigned.

MACFARLAND, R. M. D., M.Ch. Irel., has been appointed District Medical Officer, Lincoln Union, vice T. W. A. Daman, resigned.

NELSON, W. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Wootton Wawen District, Stratford on-Avon Union, vice J. Arthur, resigned.

O'REILLY, V., M.B., Ch.B. Irel., has been appointed District Medical Officer, Ormskirk Union, vice G. Morris, deceased.

PERDRAU, J. A., L.S.A., has been appointed Second Assistant Medical Officer, the Infirmary, Whitechapel Union, vice H. G. Ellery, resigned.

PINEO, E. G. D., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Churchill District, Axbridge Union, vice Dr. Box, resigned.

PRIESTLEY, THOMAS, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Sheffield Union, vice J. Somerville, resigned.

RHYS, OWEN L., M.B., Ch.B. Edin., has been appointed Resident Medical Officer to the Infirmary, Cardiff.

SASS, WILFRID, M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Great Northern Central Hospital, Holloway-road, London.

SHELDON, A. W. S., L.S.A. Lond., has been appointed Assistant Medical Officer at the Workhouse, parish of Nottingham, vice T. H. O'Shaughnessy, resigned.

SMITH, WM. ERSKINE, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the No. 4 District of the Christchurch Union, Hants.

SPARKS, C. E., M.B., B.C. Camb., has been appointed District Medical Officer, Chertsey Union, vice W. V. Robinson, resigned.

STIFF, HAROLD H., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the West London Hospital, Hammersmith-road, W.

TAUNTON, E., L.R.C.P. Lond., M.R.C.S., has been appointed Senior Assistant Medical Officer at the St. Pancras-road Workhouse, Parish of St. Pancras, London, vice T. Evans, resigned.

TELFORD-SMITH, T., M.D. Dubl., D.P.H. Camb., has been appointed District Medical Officer, Wimborne and Cranborne Union, vice C. H. W. Parkinson, resigned.

THOMAS, JOSIAH TELFER, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Camborne (Cornwall) Urban District Council.

THOMPSON, WALTER, F.R.C.S., has been appointed Honorary Surgeon to the Leeds Public Dispensary.

TICKELL, THOMAS, B.Sc. Lond., has been appointed City Analyst for Exeter.

WATKINS, J. W., M.B., B.Ch. Dubl., has been appointed Medical Officer of Health, Bolsover Urban District, vice T. W. Cole, resigned.

WEBB, WILLIAM HENRY, M.D. Durh., L.R.C.P. Lond., M.R.C.S., L.S.A., has been re-appointed District Medical Officer by the Kingsbridge (Devon) Board of Guardians.

WOOD, A. A., M.B., Ch.B. Vict., has been appointed District Medical Officer, Nuneaton Union, vice A. N. Cookson, deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House Surgeon. Salary £60 per annum, with board and attendance.

BOROUGH HOSPITAL, Birkenhead.—Three Honorary Assistant Medical Officers.

BOROUGH OF LEICESTER.—Medical Officer of Health and Public Analyst. Salary £500 per annum.

BRISTOL GENERAL HOSPITAL.—Casualty Assistant House Surgeon. Salary £50 per annum, with board, residence, &c.

CENTRAL LONDON SICK ASYLUM DISTRICT.—Two First Assistant Medical Officers for Cleveland-street or Hendon. Salary £120 per annum, with board and residence.

CHELSEA INFIRMARY, Cale-street, S.W.—Temporary Second Assistant Medical Officer (male or female). Salary £2 a week, with furnished apartments, rations, washing, coals, and gas.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist. Salary 100 guineas per annum.

DUNDEE ROYAL INFIRMARY.—Resident Medical Assistant for six months. Salary at the rate of £40 per annum, with board and washing.

FRENCH HOSPITAL AND DISPENSARY, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, speaking French, unmarried. Salary £80 a year, with full board.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley, N.B.—Senior Assistant Medical Officer. Salary to begin at £150 a year, with rooms, board, laundry, and attendance.

HAMPSTEAD HOSPITAL.—Resident Medical Officer for six months, eligible for re-election. Salary at the rate of £120 per annum, with rooms, coals, and gas.

HEIGHAM HALL ASYLUM Norwich.—Assistant Medical Officer.

HYDROPATHIC ESTABLISHMENT, Limpley Stoke.—Resident Physician, unmarried preferred.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

JESSOP HOSPITAL FOR WOMEN, Sheffield.—House Surgeon, unmarried. Salary £75 per annum, with board, lodging, and washing.

LIVERPOOL HOSPITAL FOR CONSUMPTION.—Resident Medical Officer for new Sanatorium. Salary £300 per annum, with board and apartments.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £100. Also Junior House Surgeon. Salary £80, with residence, board, &c.

LONDON HOSPITAL, Whitechapel-road, E.—Obstetric Registrar.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer, unmarried, Salary £150 per annum, with board and residence.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium £50 per annum and board.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Ophthalmic Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £60 per annum, with board, attendance, and washing. For six months, eligible for re-election as senior.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Bloomsbury.—Senior and Junior House Physician. Salary respectively £100 and £50 per annum, with board and apartments.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST, Bournemouth.—Resident Medical Officer, from April 13th to June 30th. Honorarium for the term £30, with board, residence, and washing (no alcohol provided).

NEWCASTLE-ON-TYNE DISPENSARY.—Two Visiting Medical Assistants. Salary £160 for the first year, and £180 afterwards.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician, also House Surgeon, for six months. Salary at the rate of 60 guineas a year, with board and residence.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL FREE HOSPITAL, Gray's Inn road, W.C.—House Physician, also Casualty House Surgeon for six months. No salary, but board provided. Also Clinical Pathologist, salary £75 per annum; Assistant Pathologist, salary £25 per annum; and Resident House Physician and Resident House Surgeon. No salary is given to the resident officers, but board, &c., provided. Females only.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with furnished apartments, board, and washing.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

SEAMEN'S HOSPITAL SOCIETY ("DREADNOUGHT"), Greenwich, S.E.—House Surgeon. Salary £50 per annum, with board, residence, and washing.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £24 per annum, with board, washing, and residence.

SWANSEA GENERAL AND EYE HOSPITAL.—Resident Medical Officer. Salary £75 per annum, with board, apartments, washing, and attendance.

UNIVERSITY OF GLASGOW.—Two Examiners in Medicine.

VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

VICTORIA WOMEN'S SETTLEMENT DISPENSARY, Liverpool.—Resident Lady Medical Officer.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon. Salary £120 per year and £30 per year for dispensing, with furnished apartments and attendance.

WORKHOUSE INFIRMARY, Birmingham.—Assistant Resident Medical Officer. Salary £100 per annum, with furnished apartments, rations (which do not include alcoholic liquors), coals, gas, laundry, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

HINDS.—On March 26th, at The Steyne, Worthing, the wife of Frank Hinds, M.D., of a daughter.

MCKENZIE.—On March 26th, at Glenlyon, Durban, South Africa, the wife of Archibald McKenzie, M.D. Edin., of twin daughters.

MCLAREN.—On March 24th, at Walker-street, Edinburgh, the wife of John Shaw McLaren, F.R.C.S.E., of a son.

WOLFE.—On March 18th, at The Limes, Hoe-street, Walthamstow, N.E., the wife of R. Inglewood Wolfe, Surgeon, of a daughter.

MARRIAGES.

ABBOTT—L'ESTRANGE.—On the 26th of March, at St. Gabriel's Church, Warwick-square, S.W., by the Rev. C. E. L. Beresford Knox, assisted by the Rev. Canon Morris, vicar of the parish, Francis Charles Abbott, M.S. Lond., F.R.C.S., son of the late Rev. Arthur Robert Abbott, to Pauline, third daughter of the late Lieut.-Colonel Harry Peisley L'Estrange, of Moystown, King's County.

CRAMPTON—EDE.—On March 28th, at St. Chrysostom's Church, Manchester, Cecil B. Crampton, M.B., C.M., H.M. Geological Survey, to Freda Carline, third daughter of Frederick C. Ede, of Clarendon-road, C.-on-M., Manchester.

ROWLAND—PLUMER.—On the 28th March, at Shoreham, Sussex, Frederick William Rowland, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., of 6, Waterloo-place, Brighton, to Alice, daughter of Alfred S. Plumer, Esq., of Springwells, Steyning, Sussex.

DEATHS.

DANE.—On March 27th, at Clarendon Lodge, Millbrook, Southampton, Richard Martin Dane, M.D., C.B., Inspector-General of Hospitals, Army Medical Department, retired, aged 87 years.

GROWSE.—On March 30th, at Bildeston, John Lawrence Growse, M.R.C.S., L.S.A., in his 69th year.

MORRIS.—On March 27th, at Hayes, Kent, Thomas Morris, M.D., late of the Stock Exchange, in his 83rd year.

SKENE.—On the 24th March, at Buckley, Cheshire, William Skene, M.D., F.F.P.S. Glasg., L.R.C.S.E., in his 56th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SIXTEENTH CENTURY MEDICINE

As the late John Addington Symonds justly remarks in the introduction to his admirable translation of Benvenuto Cellini's wonderful autobiography, not only was "the vehement ambitious Renaissance artist" a most veracious man, but he was also endowed with more than usual powers of observation. It will therefore be interesting, and may possibly prove instructive as well, to collate the medical matter contained in this unique record of a strenuous and exceptionally stormy career The first medical topic mentioned is the plague, from which disease Cellini believed that he suffered during his early days in Rome:—

> "I had enjoyed a very pleasant night, he says, "and rose upon the hour of breakfast feeling tired, for I had travelled many miles that night [the *travelling* is metaphorical] and was wanting to take food when a crushing headache seized me, several boils appeared on my left arm, together with a carbuncle which showed itself just beyond the palm of the left hand where it joins the wrist. I felt stifled at the heart, and made up my mind for certain that I was a dead man."

Thanks, however, to Cardinal Iacoacci s physician, who applied what are described as "admirable remedies," a great improvement soon set in, and before long the patient was able to announce his complete recovery from "that dreadful sickness" Cellini s next medical trouble was an attack of inflammation of the eyes, so painful that he "scarce could go on living for the torment." The etiology of this affection, as related by the sufferer himself, is somewhat remarkable

> "I am convinced," he said to Pope Clement VII, "that the only cause of this great affliction which has happened to me is Cardinal Salviati Immediately after your Holiness's departure he sent for me and when I presented myself he called my work a stew of onions, adding that he would send me to complete it in a galley, and such was the effect upon me of his knavish words that in my passion I felt my face in flame and so intolerable a heat attacked my eyes that I could not find my own way home Two days afterwards cataracts fell on both my eyes, I quite lost my sight, and have been unable to work at all'

A certain "great gentleman" who was present during Cellini's audience told the Pope that he could free the artist from his infirmity by the following prescription: "Take flower-de-luces, stalk, blossom, and root together, then decoct them over a slack fire, and with the liquid bathe your eyes several times a day; you will most assuredly be cured of that weakness, but see that you purge first and then go forward with the lotion"

Cellini does not tell us whether or not he made use of this aristocratic ordinance, but in his next chapter he discloses the real source of his ophthalmia:—

> "It was true indeed," he says, "that I had got the sickness, the French disease, for it was that, remained in me more than four months dormant before it showed itself, and then it broke out over my whole body at one instant. The doctors would not call it the French disease, albeit I told them why I thought it was that. I went on treating myself according to their methods but derived no benefit. At last, then, I resolved on taking 'the wood' [in a note the translator of the memoirs says: "That is guiacum (*sic*), called by the Italians *legno santo*'] against the advice of the first physicians in Rome, and I took it with the most scrupulous discipline and rules of abstinence that could be thought of The result was that at the end of 50 days I was cured and as sound as a fish in the water."

This wonderful cure, however, was unfortunately more apparent than real When the winter came in Cellini betook himself to shooting in order to "mend his shattered health," exposing himself to wind and water and to staying out in marsh lands after sundown, so that before long he felt a hundred times more ill than he had been before. Once more he placed himself under doctor's orders, attending very carefully to their directions, but instead of mending grew always worse. When he found that "the fever" was increasing he resolved on having again recourse to "the wood" in spite of the opposition of the medical men, who warned him that if he took it while the fever was still on him he would not have a week to live. In this uncompromising pronouncement the physicians were unanimous, but Cellini made up his mind to disobey them. Adopting the same strict regimen as at first, he re-commenced drinking the decoction and in four days' time was wholly rid of fever After 50 more days his health seemed to be perfectly re-established, and when at length he ventured to relax his rigid system of diet he found himself as completely clear of all bodily infirmities as if he had been born anew "I may add," says the artist in conclusion of this episode, "that during my time of severe abstinence I produced finer things and of more exquisite invention than at any other period of my life."

The most serious illness from which Cellini seems ever to have suffered befel him soon after his rehabilitation at the hands of the Pope for his murder of Pompeo, on which occasion, as he tells us, he "walked in procession very honourably between two gentlemen and so got clear at last."

Four days after this ceremony Cellini was suddenly attacked with violent fever accompanied by a sensation of extreme cold, whereupon he forthwith betook himself to bed, having made up his mind that this time at all events he was sure to die. But notwithstanding this presentiment he had the first physicians in Rome called in to attend him, among the number being Francesco Fusconi a man of great age as well as learning, who had been medical attendant to Popes Adrian VI, Clement VII, and Paul III Convinced that his malady was due to an excess of blood in his veins, Cellini had begged one Bernardino, a barber-surgeon, to bleed him, but, curiously enough, the sanguifier refused to do so, and by the time that Maestro Francesco took charge of the case the opportunity for venesection, according to the latter, had gone by Cellini grew rapidly worse:—

> "Nature in me," he says, "was utterly debilitated and undone I had not strength enough to fetch my breath back if it left me, and yet my brain remained as clear and strong as it had been before my illness Nevertheless, although I kept my consciousness, a terrible old man used to come to my bedside and make as though he would drag me by force into a huge boat he had with him"

Several of the sick man's friends having come in to talk with him and comfort him, one of the number, Messer Ludovico, asked him what it was he seemed to see and how the man was shaped. "While I was portraying him in words," says Cellini, "the old man grasped me by the arm and dragged me violently towards him This made me cry out for help, because he was going to fling me down under hatches in his hideous boat. On saying that last word I fell into a terrible swoon and seemed to be sinking into the boat." During this "fainting fit" the patient was very violent, throwing himself about and casting bad words at some of the bystanders whose presence displeased him, but later he lay still like one dead, and after waiting beside him more than an hour the attendants, supposing him to be growing cold, left him for dead Felice, his faithful friend and partner, alone remained, but when three hours more had passed without any change, and the five separate remedies that had been prescribed by Maestro Francesco were all expended, he ran off post-haste to the latter's door and set to knocking with such vigour that he made him rise from his bed. Then, with tears in his eyes, the energetic applicant implored the physician to come to his patient, for in sad truth he believed he was dead. Upon this Maestro Francesco, who was a very choleric man, replied: "My son! Of what use do you think I should be if I came? Do you imagine that if I were to come with my medicine I could blow breath up through his guts [Cellini makes the irate physician employ a still more forcible word] and bring him back to life for you?" When, however, the worthy, though sleepy, old physician saw that the poor young fellow was going off weeping he called him back and gave him an oil wherewith to anoint Cellini s failing pulses and heart, directing him also to pinch the little fingers and toes of the moribund very tightly and to send at once and call him if he should revive. Felice duly carried out his orders but without effect. When day broke all hope was abandoned Directions were given to prepare the dead man's shroud and to set about washing his corpse. Upon this Cellini incontinently regained consciousness and began shouting to Felice to drive away the old man who would keep on tormenting him. Felice promptly approached the bed, making believe to obey and extending protecting arms Cellini seized hold of one and forthwith it seemed to him that the objectionable phantom withdrew overcome by fear He accordingly begged his friend not to leave him for a moment, seeing that the dreadful old creature was manifestly afraid of him. When Maestro Francesco came he declared he had never in all his days seen greater vital force in a man old or young than Cellini exhibited. Then he sat down to write and prescribed perfumes, lotions, unctions, plasters, and a heap of other things of price and rarity, but what really brought the sick man to life is described as "more than 20 leeches applied to his buttocks." Many people are said to have crowded in to behold the miracle of a resuscitated dead man, but, according to the ex ghost himself, what they saw was "a body bored through, bound, and ground to powder."

And yet, in spite of all these wonderful doings and sayings, Cellini's "wretched malady went dragging on and he got but little better. Attendants and visitors vied with each other in their attentions and suggestions on behalf of the sick man, while his chief physician, that most excellent man Maestro Francesco, came four or five times a day He and the other physicians were at the end of their wit and learning"

Cellini was "tormented by thirst," but abstained from drinking in compliance with the strict injunctions of his medical men. One day Felice went out leaving the patient under the care of a servant-maid called Beatrice. This girl, as it happened, "had stolen certain little things of some importance, and in her fear of being detected would have been very glad if her master had died." A great crystal vase was standing hard by full of clear and fresh water:

> "If you will bring it here and let me drink to my heart's content," said Cellini, who was overcome by drouth, "I will give you a new gown. At once the girl ran to fetch the vessel, and carrying it to the bedside she put the brimming margin to my lips. Twice did she allow me to drink my fill, so that in good earnest I swallowed

> more than a flask full (upwards of a quart). Then I covered myself up and immediately began to sweat. In a few moments I fell into a deep sleep."

When Felice returned and learnt what had happened he began to beat the maid so severely that she set to screaming. The noise she made woke Cellini who cried out: "Leave her alone; perhaps when she meant to do me harm she did me more good than you were able to do with all your efforts. She may indeed have saved my life, so lend me a helping hand, for I have sweated, and be quick about it."

This seems to have been the turning point in a somewhat mysterious disease. When Maestro Francesco next came:—

> "That most able man (who was not above owning himself mistaken) exclaimed: 'Oh, power of Nature! She knows what she requires and the physicians know nothing.' Whereupon that simpleton Bernardino made answer: 'If he had drunk another flask he would have been cured on the spot.' Turning to me, says Cellini, Maestro Francesco asked me if I could have drunk more water. 'No!' I replied, 'because I had entirely quenched my thirst.' Then turning to Maestro Bernardino the venerable physician cried: 'Look you now how Nature has taken precisely what she wanted, neither more nor less. In like manner she was asking for what she wanted when the poor young man begged you to bleed him. If you knew that his recovery depended upon his drinking two flasks of water why did you not say so before? You might then have boasted of his cure.' On hearing these words the miserable quack sulkily took himself off and never showed his face again."

Under orders from Maestro Francesco, Cellini was taken with great precautions in a chair, well wrapped up and protected from cold, to a house on Monte Cavallo belonging to Cardinal Cornaro.

> "No sooner had I reached the place," he says, "than I began to vomit, during which there came from my stomach a hairy worm about a quarter of a cubit in length; the hairs were long and the worm was very ugly, speckled of divers colours, green, black, and red. They kept and showed it to the doctor who said he had never seen anything of the sort before."

This serious illness of Cellini lasted during "more than 50 days" in an acute form and a long time passed before he was completely restored to his customary good health. There is no hint to that effect in the memoirs, but it seems possible, if not probable, that the turbulent artist may have been poisoned out of revenge by the adherents of his victim Pompeo, the Milanese jeweller, whom he killed by "two stabs with a poniard in the throat in the midst of 10 men who were guarding him." Be this as it may, save for the present attack, whatever it may have been, Cellini always enjoyed the most robust health, even during his prolonged and cruel imprisonment in a water-logged dungeon, the only other illnesses mentioned in his autobiography being *una febbre efimera* (a fever of one day's duration) brought on by excitement while the casting of his famous statue of Perseus was in progress, and an "indisposition" caused by the unwholesome air at "a very handsome place called Belfiore, close under the city walls" at Ferrara. The way in which Cellini got the better of the last-mentioned sickness is remarkable from more points of view than one. Observing that the domain was haunted by multitudes of peafowl which bred and nested there in a state of freedom the idea came into his head to charge his gun with "a noiseless kind of powder"; then he tracked some of the young birds and every other day shot one which furnished him and his companions with an abundance of meat of such good quality that they speedily shook off their indisposition.

In the matter of accidental injury Cellini did not come off altogether scatheless. While effecting his escape in such a marvellous way from the Castle of Sant' Angelo, where Pope Paul III. had incarcerated him, his "right leg was broken three inches above the heel" (doubtless a case of Pott's fracture). The great hardships he underwent for a considerable time afterwards were little calculated to conduce to such a good ending, but thanks to "Maestro Jacomo of Perugia, a most excellent and able surgeon," who set the bone with much dexterity, the intrepid fugitive eventually recovered perfectly. Once as he was working on a statue of Narcissus Cellini tells how

> "A very fine splinter of steel flew into my right eye and embedded itself so deeply in the pupil that it could not be extracted. I thought for certain that I must lose the sight of the eye, but Maestro Raffaello de' Pilli succeeded in effecting a cure, although he was not called in until several days after the accident. Having obtained a couple of live pigeons he placed me on my back across a table. Then he took the birds and opened a large vein they have beneath the wing, so that the blood gushed out into the injured eye. I felt immediately relieved and in the space of two days the splinter came away and I remained with my vision greatly improved."

Cellini's experience of poisons was, as might be expected, very considerable. While he was the Pope's prisoner an attempt was made, he says, to get rid of him by

> "Mixing pounded diamond with my victuals. Now the diamond," he adds, "is not a poison in any true sense of the word, but its incomparable hardness enables it, unlike ordinary stones, to retain very acute angles. When other stones are pounded that extreme sharpness of edge disappears, the fragments becoming blunt and rounded. The diamond alone preserves its trenchant qualities, wherefore if it chances to enter the stomach together with food the peristaltic motion needed for digestion (*In quel girare che é fanno é cibi*) brings it into contact with the coats of the stomach and the bowels where it sticks, and by the action of fresh food forcing it farther inwards after some time the organs become perforated. Thus eventually death is caused."

According to Cellini, the preservation of his life on this occasion was due to the covetousness of the miscreant who had been hired by his enemy to carry out the nefarious plot. In lieu of the brilliant worth more than 100 crowns which was intrusted to him to pound this individual substituted "a greenish beryl of the value of two carlins, thinking, no doubt, that because it also was a precious stone it would work the same effect as a diamond." Another attempt to poison Cellini took place towards the close of his career, the motive in this case being the sordid one of robbery. The artist having bought a farm from one Piermaria d'Anterigoli, surnamed Lo Sbietta, on condition that at his death the property was to revert to its original owner, the latter, with the assistance of his wife, tried to bring about the purchaser's speedy demise by administering a quantity of "sublimate" in some highly-spiced sauce. The woman, by her assiduity in pressing him to partake of the condiment, fortunately excited the victim's suspicion, and it was also Cellini's "custom to take but little sauce or seasoning with his meat, excepting salt," and so he escaped.

> "The quantity of poison I swallowed," he says, "was not enough to kill me, but exactly sufficed to cleanse me of a mortal viscosity from which I suffered in my stomach and intestines. ...... The poison worked so well that whereas before I took it I had perhaps but three or four years to live, I verily believe now that it has helped me to more than 20 years by bettering my constitution. For this mercy I return thanks to God with greater heartiness than ever; and this proves that a proverb I have sometimes heard spoken is true, which runs as follows: 'God sends us evil that may work us good.'"

"MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB."

"PLACE OF RESIDENCE FOR A RETIRED SURGEON."

To the Editors of The Lancet.

Sirs,—Will you permit me, in reply to "P. P.," whose communication appeared in The Lancet of March 30th, p. 937, to say that having now practically retired I find Bournemouth exceedingly pleasant, physically and socially. Branksome is nearly equally desirable, and rents and taxes are very much cheaper. It is quite as healthy, there is more country as well as the advantage of the park, and it is within walking distance of Poole Harbour and shipping. You can get into Bournemouth from Branksome by rail or tram in about 10 minutes for a few pence.

I am, Sirs, yours faithfully,
Bournemouth, March 30th, 1901. F. H. A.

WANTED—A HOME.

To the Editors of The Lancet.

Sirs,—Can any of your readers recommend a home for a girl, aged 16 years, of weak intellect? The friends can pay a small fee.

I am, Sirs, yours faithfully,
Ash Cottage, Hindley, March 30th, 1901. J. Chronnell.

THE PRINCE CHRISTIAN VICTOR MEMORIAL FUND.

The following sums, additional to those which have already been announced in the daily press, have been received for the Prince Christian Victor Memorial Fund for endowed beds for disabled soldiers and sailors in the Princess Christian Homes (Memorial Office, Horse Guards, S.W.):—Mrs. S. Lewis, endowed bed, £600; Mrs. Bischoffsheim, £50; Miss Dawson Lambton, £25; Miss E. Dawson Lambton, £25; Mr. A. Moseley, £21; Lord and Lady Llangattock, £20; £10 10s. each Mr. John Fairbank, Mr. H. Oppenheim, and Miss Tidswell; £10, Anon, Major-General Blundell, General Sir R. Buller, Major Hon. F. L. Colborne, Earl of Cranbrook, Earl of Elgin, Lady Susan Leslie Melville, Mr. Pandeli Ralli, Lord Justice Romer, Right Hon. A. H. Smith Barry, and Mrs. Smith Barry; £5 5s., Mrs. Erle, Viscount Knutsford, Mrs. C. Lancaster, Captain C. B. Levita, Colonel R. Parry Nisbet, and Sir R. Douglas Powell; £5, Mrs. Adeane, Lord Aldenham, Colonel Donald Browne, Lady

Victoria Buxton, Duchess of Cleveland, Sir James Colquhoun, Hon. Mrs. Dillon, Dowager Lady Hillingdon, Lord Knutsford, Captain M. A. Laing, Rev. K. E. B. Maires, Duke of Montrose, Miss Penny, Earl of St. Germans, Mr. George Scott, Lord Thring, Major-General Swaine, and Mrs. Robert Wingate; £4 4s., Sir Hugh and Lady Wyndham; £3 3s, Dr. T. Miller Maguire and Mr. F. D. Mocatta; £3, Constance Marchioness of Lothian and Mrs. William Rickman; £2 2s., Mrs. E. Blathwayt, Hon. T. A. Brassey, General Dunne, Messrs. Helmers and Sons, Mr. R. Y. Kennedy, Messrs. Lloyd, Mr. C. P. Penny, Mr. E. K. Purnell, and the Bishop of Rochester; £2, General E. M. Cherry, Mrs. C. L. Foquette, Countess of Lytton, Countess of St. Germans, Private A. Williams (collected), Mr. V. C. Smith, and Colonel Turbervill; £1 1s., Mrs. Y. H. Beevor, Captain Clarke, Mrs. Emerson, Hon. Mrs. Kennedy, Mrs. C. R. Jackson, Mrs. Mackenzie, Mr. C. S. Matthews, Hon. Mrs. Talbot, Mrs. Charles Thynne, and Mr. F. R. S. Wyllie; £1, Lady Colville, Lady Fletcher, Miss Maxwell, and Miss S. E. H. Noyes; 16s., Miss Rooper; 10s. 6d., Miss A. M. Courtenay, Miss L. Courtenay, H B. D., Miss F. H. Fisher, Dr. Kelly, and Mr. B. S. Ogle; 10s., Dr. Alderson. A Reader of the *Scottish Guardian*, A Scotch Woman, R. Y. R., and Mrs. Hawkins; 5s., Miss Butler, Miss M. Chute, and Miss M. Edwards.

◆

Jay Pay.—We have not seen the book in question. There is, of course, difficulty in securing conviction against a man for publishing obscenity if he can set up anything in the nature of a defence. As a rule it is hard to find a prosecutor, the police rarely taking the initiative, and private individuals are not willing to do the unpleasant work.

Virtus.—Our correspondent is referred to an annotation on the subject which appeared in our last issue on page 952 and in which we state our views of the matter.

Blushing.—We cannot recommend any treatment.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Cheques and Post Office Orders (*crossed* "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Hunterian Lectures

ON

THE TOPOGRAPHICAL ANATOMY OF THE ABDOMINAL VISCERA IN MAN.

Delivered before the Royal College of Surgeons of England on March 4th, 6th, and 8th, 1901,

BY CHRISTOPHER ADDISON, M.D. LOND.,
F.R.C.S. ENG.,
PROFESSOR OF ANATOMY AT THE UNIVERSITY COLLEGE, SHEFFIELD

LECTURE III[1]

Delivered on March 8th

THE PERITONEUM ON THE CÆCUM

MR PRESIDENT AND GENTLEMEN,—In four cases bands of various sorts ran along the back of the cæcum, but none of them represented a true meso cæcum The peritoneum as it was reflected from the back of the cæcum or the ascending colon on to the body wall externally presented in many cases a well marked fold passing to the upper part of the iliac crest

THE PERITONEAL FOLDS AND POUCHES IN THE NEIGHBOURHOOD OF THE ILEO COLIC JUNCTION,

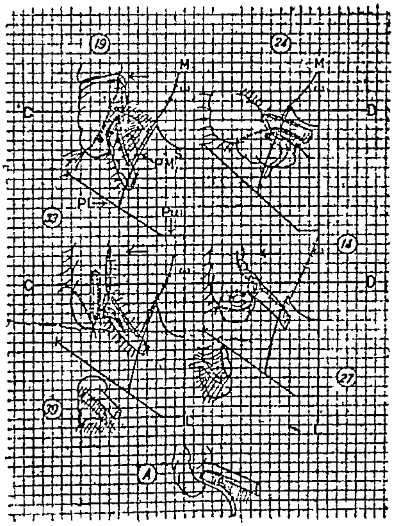
These were so fully described by Mr. B G A Moynihan[2] of Leeds in his lectures two years ago that very little need be said concerning them (see Fig 8) There are three, or sometimes four, folds to be considered, and three, or sometimes four, fossæ We will adopt a nomenclature after Lockwood and Rolleston and Berry and speak of them as. (1) the ileo colic fold and fossa, (2) the ileo-cæcal fold and fossa (or ileo appendicular), (3) the meso appendix, and (4) the retro-colic fold and fossa (occasionally two fossæ, internal and external) Very diverse and perplexing are the names and descriptions given to these folds and fossæ by some writers It seems needlessly so

1 *The ileo-colic fold and fossa* —There is nothing to add to the current descriptions of this fold There were only five cases in which it was specially drawn as bounding well-defined and considerable fossæ, and the many other cases in which it was present were passed over, as the detailed examination and record of these fossæ did not form a part of this research Case 19, Fig 8, shows this fossa very well.

2 *The ileo-cæcal fold and fossa* (Fig. 8, outline A) —In most fat subjects this fold contains a considerable amount of fat and in some cases it was described as loaded with fat A small recurrent branch of the appendicular artery is often found in it, so that Mr Treves's[3] description of it as the bloodless fold is not always applicable In 24 cases, or 60 per cent, the fold was well marked, bounding more or less well defined fossæ in 23 of them The superior border of the fold is attached for a variable distance (usually about four centimetres) along the ileum at its termination, the outer border—directed somewhat upwards—is attached to the cæcum, the lower border is attached to the back of the cæcum, adjoining the appendix, to the appendix itself or to the meso-appendix for a variable distance; whilst the internal border directed downwards and inwards with various obliquities is free, somewhat crescentic, and longer than the others

3 *The meso appendix.*—The original attachment of the meso appendix to the back of the mesentery is progressively displaced by the growth of the cæcum and colon to the back of the large intestine The positions of the attachments of the meso appendix classified on this basis occurred in the 40 cases [illegible] (1) wholly to the inferior [illegible] it cases; (2) partly to the me[illegible] the cæcum, 13 cases, (3) w[illegible] or ascending [illegible] specially in those cases in [illegible] was more or less marked), [illegible] three cases where the appendix was bound by peritoneum to the back of the large intestine and one case in which it was bound to the floor of the iliac fossa The long or free border of the meso appendix can usually be traced as a small sickle shaped band almost to the extremity of the appendix

FIG 8.



St[illegible] the commencement of the [illegible] the text)

4 *The retro colic fold and fossæ* (Fig 8, Cases 19 and 33) —Berry[4] divides the fossæ behind the cæcum or the beginning of the ascending colon into the internal and external In these cases only one—the internal—appeared to be of any consequence A fold of peritoneum passing to the back of the cæcum or the first part of the ascending colon frequently divides the region behind the large intestine at this part, external to the mesentery and the meso appendix, into inner and outer parts The outer part may be converted into a wide pocket by the reflexion of the peritoneum at a higher level from the back of the ascending colon on to the body wall near the upper part of the iliac crest giving it a definite upper limit Except in five cases such an external retro-colic pouch was so wide and shallow that it could not fairly be called a pouch In one case only was it so well defined that it might possibly have become of clinical importance The appendix does not pass into it

The internal or proper retro colic pouch is of much importance It was well defined in eight cases, or 20 per cent It often contains the root of the appendix and occasionally the appendix is wholly or partly recurved into the pouch A glance at Fig 8 (Case 33) shows quite well how in such a case further absorption of the peritoneum by the colon would have produced an appendix wholly behind the peritoneum, as in Case 14 Case 27 shows an interesting position of the appendix The greater part of it was firmly bound by peritoneum to the back of the large intestine; the root of the appendix was situated behind the cæcum and the tip projected from out of a pouch external to the ascending colon at the level of the iliac crest The case apparently represents an appendix which was recurved upwards outside the reflexion of the peritoneum on to the back of the ascending colon, the peritoneal folds having become obliterated at its proximal part

---

[1] Lectures I. and II were published in THE LANCET of March 16th (p. 759) and 30th (p 911), 1901, respectively

[4] The Cæcal Folds and Fossæ, &c., Edinburgh, 1897

THE PERITONEUM ON THE COLON.

There were six cases, or 15 per cent, which presented an ascending meso-colon and nine cases, or 22 5 per cent., which presented a descending meso-colon. The figures are somewhat less than those that Treves[5] gives, but it must be remembered that they only refer to those cases in which the folds were definitely existent. There were doubtless other cases in which for surgical purposes an ascending or descending meso colon was as good as present.

Cases 8, 18, and 38 were excellent examples of an ascending meso-colon and it is interesting to notice that in all of them a long free appendix passed upwards behind the colon external to the attachment of its mesentery (see Case 8, Fig. 10). The distance of the attachment of the meso-colon from the middle line as shown by the dotted line in the figure was that of the average position of the normal peritoneal reflexion on to the inner side of the ascending colon. A similar description applies to the line of the attachment of the meso-colon in eight of the nine cases in which a descending meso-colon existed.

THE CYSTO COLIC FOLD.

There were 12 cases, or 30 per cent., in which this fold, which I have previously described, was present. In all but two of them there existed that which will be described as the first and chief variety of the transverse colon—viz., one characterised by a marked and more or less firm downward hepatic loop.

THE MESO-SIGMOID.

In connexion with the meso-sigmoid (Fig. 9) it cannot be too much emphasised that the sigmoid flexure of the colon over the left psoas muscle has a very short mesentery. In fact, in most cases, this part of the intestine is firmly bound down by the peritoneum. The free part of the sigmoid colon, hanging into the pelvic cavity or having a free excursion in the abdomen, is that which has its mesentery attached passing upwards along the inner border of the left psoas muscle from about the plane of the anterior superior iliac spines.

The normal meso-sigmoid, as represented in Fig. 9, Case 17, consists of two limbs. The *outer limb* begins over the left psoas muscle about the plane of C, D,[6] and passes inwards and downwards to a point just internal to the left lateral line, a little above the level of the anterior superior iliac spine, from which it turns upwards as the *inner limb* along the inner margin of the left psoas muscle to the upper part of the little recess between the psoas muscle and the side of the vertebral body bounding the lumbo-sacral promontory. Here it often presents a sharp bend with the convexity upwards and then passes downwards on the side of the vertebral body, or across the little recess, into the pelvic cavity, where, as the meso-rectum, it is placed about two centimetres from the middle line. The degree of prominence of the upward bend depends upon the state of the development of an up-going fold, which Robinson[7] describes as the suspensory ligament of the meso-sigmoid (outline 14, Fig. 9). When the fold is absent the inner part of the meso-sigmoid may become straightened out. The commonest variation of the meso-sigmoid is the obliteration either by adhesions or by bowel growth of its outer limb (Case 18, Fig. 9), leaving the inner portion Λ-shaped.

In these 40 cases these conditions occurred with the following frequency:—1. Presence of both limbs, 27 cases, or 67 per cent. 2. Complete absence of the outer limb, 11 cases, or 27·5 per cent. 3. Abnormal cases in the presence of a descending meso-colon, two cases.

In the first set of 27 cases there were 13 in which the outer limb of the meso-sigmoid was so short that the attached part of the bowel was practically immobile. So that in 24 cases altogether, or 60 per cent., the outer (first) part of the sigmoid flexure of the colon was firmly fixed. In five cases the inter-sigmoid pouch was very well marked. Case 18 (Fig. 9) shows a kink on the descending colon where it was lodged in a pocket behind the outer part of the psoas muscle at the upper part of the iliac fossa. The bowel was tightly bound in this pocket by the peritoneum. A similar condition existed in two other cases

THE LARGE INTESTINE.

The vermiform appendix.—The root of the appendix is situated in the average in the right lateral line midway between the planes of C, D, and the anterior superior iliac spines, or about an inch below the intersection of the right lateral line and a line drawn from the right anterior superior iliac spine to the umbilicus. *High level.*—There were four cases in which the *root* of the appendix was situated above the plane of C, D. In two of them it was carried up by a very distended cæcum which would have been obvious on superficial examination, and in the other two cases the ascending colon had very loose peritoneal attachments. In five other cases the *tail* of the appendix passed upwards above the level of C, D. In three of these the appendix was directed upwards in a retro-colic pouch and in the other two cases outside an ascending meso-colon. In one case it was very large and reached up to the under surface of the liver. In nine cases, therefore, or 22·5 per cent, the appendix was situated wholly, or in part, above the level of C, D. *Low level*—In seven cases the root of the appendix was at or below the level of the *anterior superior iliac spine*; in all of the cases the cæcum was distended and in four of them it was prolapsed within the pelvic cavity. In four cases the root of the appendix was less than four centimetres from the middle line. In three of the cases the cæcum was wholly, and in the other case partly, prolapsed into the pelvic cavity (Case 7, Fig. 10). The alterations in the positions of the appendix as a whole are specially associated with a distended condition of the cæcum and the appendix is specially likely to be found high up when the attachments of the ascending colon are lax. The position of the appendix in relation to the cæcum is chiefly determined by the degree of the absorption of its mesentery by the cæcum or colon. The tenseness of the peritoneum on the iliac fossa no doubt determines the degree of possible prolapse of the cæcum. In a general way the appendix hangs either partly or wholly over the margin of the psoas into the pelvic cavity. The direction of its free end is evidently a matter of small importance as it will vary from time to time. The positions of the vermiform appendix fall into four groups, and in these cases they occurred with the following frequency: 1. Wholly within the pelvic cavity, six cases, or 15 per cent. 2. Free, hanging more or less over the pelvic brim, 16 cases, or 40 per cent. 3 Wholly in the iliac fossa, 14 cases, or 35 per cent. Of these cases seven were quite free, four were partly free but recurved into a retro-colic pouch, and three were wholly behind the peritoneum. 4. Irregular cases, four, or 10 per cent. In three of the irregular cases the appendix passed upwards, as has been described, outside an ascending meso-colon and in the fourth case it was bound to the back of the cæcum without any apparent mesentery. (Fig. 8, Case 39) If we combine these cases we see that in eight instances, or 20 per cent., the appendix was either recurved into a retro-colic pouch or was firmly fixed behind the peritoneum.

THE CÆCUM.

The lowest point of the cæcum was situated, as a rule, in the right lateral line about half an inch below the level of the anterior superior iliac spine. There were seven cases in which the cæcum was wholly, and three cases in which it was partly, prolapsed into the pelvis, or 25 per cent. of the total cases. The chief features in these cases were a distended condition of the cæcum and a generally convoluted condition of the large intestine. In six cases the cæcum was displaced more or less completely above the level of C, D. In these cases, again, distension was a marked feature and frequently a lax state of the attachments of the ascending colon. (See Cases 8 and 12, Fig. 10.) In both these groups of cases the ileo-colic junction was lower down or higher up than usual in conjunction with the cæcum. The cases generally hardly warrant one in saying more than that when the large intestine generally is voluminous and convoluted the cæcum in the presence of distension will be more likely to find room for itself in the pelvis than in the abdomen. In many of the cases of distension of the cæcum when it was not prolapsed, as in Case 12, the beginning of the large intestine presented a twist-like appearance as if the lower part had passed upwards in front of the upper part, so that, it may be, the lowest part of the bowel is not cæcum but colon. The condition was evidently produced by the firm peritoneal attachment of the ascending colon about the level of the iliac crest to which I shall direct your attention in a moment. The bowel above the ileo-colic junction in these cases was firmly fixed, the lower distended part passing

---

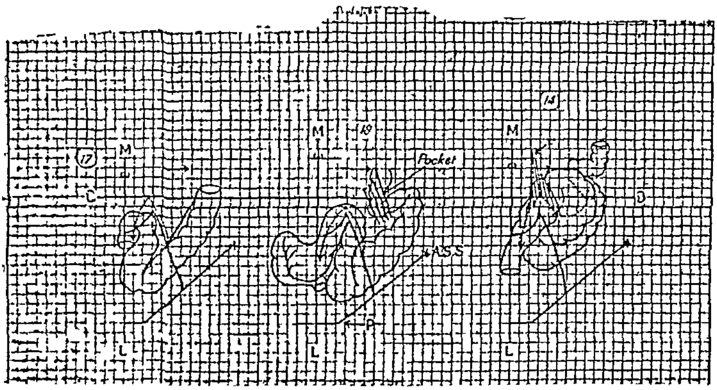
[6] Readers are reminded that the plane C, D, is one taken transversely across the abdomen a quarter of the way from the upper border of the pubes to the supra sternal notch

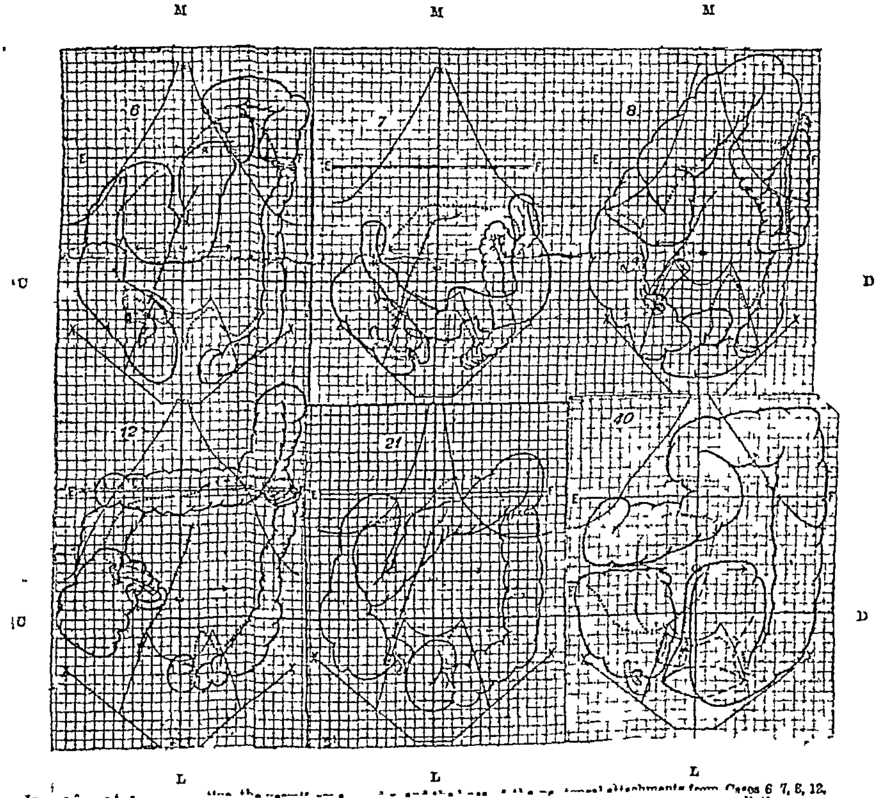
[7] Robinson Byron The Sigmoid Flexure, &c., Matthew's Medical Quarterly, Louisville, vol. iii., 1896

FIG 9



Shows the three types of the meso-sigmoid described in the text. In the outline from Case 17 the outer limb of the meso-sigmoid is shown by a line and the rest of its attachment in this figure as in the outlines from Cases 18 and 14 is shown by a dotted line In Case 18 the commonest abnormality of the absence of the outer limb of the meso-sigmoid is shown and in Case 14 the suspensory fold is shown. The scale represents centimetres C, D, the lower transverse abdominal line M, L the middle line.

FIG. 10



In [illegible] attachments from Cases 6 7, 8, 12, [illegible] F, the upper, [illegible] wards from it, [illegible] ows the two [illegible] the os pubis, [illegible] e dotted line [illegible] upwards anteriorly. The third and fourth types of cæcum of Treves are apparently chiefly and nearly equally represented in these cases.

THE ASCENDING COLON.

The distance of the outer border of the ascending colon from the middle line did not present much variation. In 34 cases, or 85 per cent., it varied from ·10 centimetres to 12·5 centimetres from the middle line in the plane of C, D. In nine cases, or 22·5 per cent., the ascending colon about the level of the highest part of the iliac crest had a well-defined kink in it, brought about by its being in these cases strongly bound to the back abdominal wall by its peritoneal attachments. In some cases, as in Case 40 (Fig. 10), these were sufficiently strong to bar effectually the distension of this part of the bowel, although the neighbouring parts were very distended.

THE TRANSVERSE COLON.

There appear to be two chief varieties in the shape of the transverse colon, determined by the presence or absence of a loop downwards from the hepatic flexure. 1. The loop appears to represent a permanence or exaggeration of the primitive bend of the colon at this place. There were 22 cases, or 55 per cent., which presented this loop in varying degrees. In them, as in Case 21 (Fig. 10) the transverse colon at its beginning bends more or less directly downwards for a variable distance (mostly as far as the level of the iliac crest) in front of and to the inner side of the ascending colon, and then, passing upwards again nearer to the middle line, it completes the hepatic loop downwards and passes more or less obliquely across the abdomen to the left side. At the left side, under cover of the ribs, the colon rises for a variable distance upwards in a loop usually directed on an antero-posterior plane. The posterior, or down-going, limb of the loop, when it reaches the basal surface of the spleen, is directed backwards to the posterior abdominal wall, where it turns abruptly downwards as the descending colon. The hepatic loop downwards of the transverse colon is often firmly fixed and difficult to undo; and its down-going limb is frequently found adherent to the adjacent ascending colon. The relatively more stable condition of the bowel contents at the extremity of this down-going loop may perhaps favour the formation of these adhesions. 2. In nine cases, or 22·5 per cent., of which No. 12 (Fig. 10) is an example, there was complete absence of the downward hepatic loop and the transverse colon passed from its hepatic flexure directly across the abdomen along the under surface of the liver to the left, or bulged forwards in a horizontal plane before passing to the left. There were, of course, many cases in which the transverse colon presented shapes intermediate between these looped or straight varieties. In 27 cases, or 67 per cent., the splenic loop upwards had a sagittal direction, of which Case 8 is a good example. In seven cases, or 17·5 per cent., this splenic loop passed in a coronal plane, of which Case 6 is a good example. The down-going limb of the splenic loop is usually of a smaller calibre and more closely sacculated than the rest of the transverse colon. Like the beginning of the ascending colon, the termination of the transverse colon at the posterior part of the basal surface of the spleen is often so firmly fixed that it will not share in general distension of the large intestine. (See Case 6, Fig. 10.)

The cases of high position of the hepatic flexure of the colon and of the transverse colon in the middle line have been already referred to in considering high positions of the stomach, and need not detain us. There were six cases in which the upper border of the transverse colon in the middle line was from 2·5 to nine centimetres above E, F,[8] and 14 cases in which it was from five to 15 centimetres below it, so that it must be considered a very variable point and the average cannot be taken for much. There were, however, 20 cases, or 50 per cent., in which the line E, F, would have hit off sufficiently some part of the lumen of the bowel over the middle line.

Prolapse of the transverse colon (Case 7, Fig. 10, or Case 24, Fig. 11).—There were six cases in which the transverse colon passed across the abdomen wholly below the umbilicus, and four others in which the umbilicus was nearer its upper than its lower border, giving 10, or 25 per cent., of the cases in which the transverse colon crossed the middle line wholly or in greater part below the umbilicus. In five of these cases the attachment of the transverse meso-colon was as high, or in one case (Case 4) higher, than usual; so that in them the low position of the bowel was associated with an elongated, not a prolapsed, mesentery. The average level of the attachment of the transverse meso-colon in the middle line was three centimetres below E, F, and at its commencement at the right, 6·45 centimetres below E, F, or three centimetres above the highest point of the iliac crest. Sometimes the attachment at the right may be low down, whilst that over the middle line is as high as usual; but the low attachment at the right may be sufficient to allow of prolapse of a great part of the transverse colon.

If we define, for convenience' sake, prolapse of the transverse colon and of its mesentery, as when the upper border of the bowel or the attachment of its mesentery in the middle line is five centimetres or more below E, F—that is, about two inches above the highest part of the iliac crest—we have 14 cases of prolapse of the transverse colon and eight cases of prolapse of the transverse meso-colon more or less considerable. Seven cases are common to the two groups. In these cases it will be found that a low position of the liver, and in many cases of the stomach, is especially noticeable. In fact, it seems difficult to lay too much stress on the displacing power of the liver over the parts of the alimentary tract in its neighbourhood. (Fig. 11 shows the position of the parts from Case 24.) In some of the other cases of prolapse of the transverse colon, however, as has been previously noticed, the stomach was at its usual level, the peritoneum between the stomach and the transverse colon having become elongated.

THE DESCENDING COLON.

The inward (and usually firmly-fixed) bend of the descending colon at the lower end of the left kidney was well marked in 12 cases, or 30 per cent., as in Case 7. In three cases the descending colon passed downwards into a pocket beneath the outer border of the psoas muscle and was firmly fixed there by the peritoneum and the bowel took a sharp bend upwards and outwards round the muscle before passing downwards as the sigmoid flexure. (See Fig. 11.)

THE SIGMOID FLEXURE.

The sigmoid flexure passes downwards, more or less firmly bound to the left psoas muscle, in a curve with its convexity outwards, situated about three centimetres internal to the anterior superior iliac spine, until it reaches the brim of the pelvis and becomes possessed of a longer mesentery and acquires a considerable degree of mobility. *For practical purposes a point in the left lateral line at the level of the anterior superior iliac spine may be taken to correspond to some part of the lumen of the sigmoid flexure at the place where it thus, somewhat abruptly, becomes freely moveable.* Treves's[9] description of an omega-shaped loop of the sigmoid flexure within the pelvis represented the majority of cases. There were eight cases, or 20 per cent., in which a large loop of the sigmoid flexure extended out of the pelvis into the umbilical or the right or left iliac region. In these cases the bowel consisted for the most part of a simple loop which was usually distended. A study of the rectum did not enter into this work.

THE LIVER.

So much has been said in the previous lectures about the solid viscera in the upper part of the abdomen, and the time at our disposal is so limited, that I can only notice a few points. Further details of the surface-marking of the liver may be passed over, especially as the dimensions of this organ can often be determined by the methods of physical examination. In the series of cases examined there was an unusually large number of instances in which the liver was either displaced from intra-thoracic pressure or in which it was enlarged, so that the position of its lower border as shown in Fig. 2, Lecture I., is in all probability one centimetre lower than it would be in the average healthy body. Fig. 3 (Lecture I.) shows that the right costal margin from a level midway between E, F, and the infra-sternal notch to a point four centimetres outside the right lateral line practically represents the lower boundary of the hepatic surfaces of the right kidney and suprarenal capsule. The average distance of the outer border of the inferior vena cava beneath the liver from the middle line was 3·6 centimetres and in very many cases the spigelian lobe of the liver extended inwards beneath the vessel so as almost to make a complete tunnel for the vessel in the liver substance. In 30 cases, or 75 per cent, the right lateral line traversed some part of the fundus of the gall-bladder, or was within one centimetre of one of its margins. In seven cases the gall-bladder did not project beyond the lower border of the liver.

---

[8] The plane E, F is one transversely across the abdomen through a point half-way from the upper border of the pubes to the suprasternal notch.

THE RIGHT KIDNEY.

One remark may be added to the general description of the surface marking of the right kidney given in the first lecture—namely, that from the point of intersection of the right lateral line with E, F, the upper pole of the kidney was one and a half inches vertically upwards and its outer border the same distance transversely outwards The variations in level of the upper pole of the right kidney may be considered both in regard to the surface line E, F, and to the disc between the first and second lumbar vertebræ In 21 cases, or 52·5 per cent, the upper pole of the kidney was situated between two and 4·5 centimetres above E F, inclusive In eight cases it was lower than this, the lowest being on the level of E, F (Case 20) In 11 cases it was more than 4·5 centimetres above E, F, the highest being eight centimetres in Case 10

The disc—On the other hand, there were seven cases in which the upper pole of the kidney was not more than one centimetre above the disc—down to one centimetre below it (in Case 20). The average was 3·7 centimetres above the disc There were 11 cases in which it was 5·5 centimetres or more above the disc up to nine centimetres above (in Case 10) We find, therefore, that the variation in position of the upper pole of the right kidney compared to E, F, was eight centimetres—from the same level to eight centimetres above—and compared with the first lumbar intervertebral disc 10 centimetres—from one centimetre below to nine centimetres above These figures again confirm the value of the surface line and they show us incidentally how considerable are the variations in level of the kidney compared with the vertebral column.

In inquiring what relation exists between the levels of the liver and the right kidney we may compare the level of the upper border of the liver in the right lateral line with that of the upper pole of the right kidney; and whatever displacing power the liver may possess it is more likely to be seen in the extreme cases, so that we will place side by side those cases in which the liver occupied a low position and those in which it was high up The average distance vertically upwards from the upper pole of the right kidney to the upper border of the liver in the right lateral line was seven centimetres. The following table records these distances in two cases: A, where the liver was lowest down, and B, where it was highest up

A.		B.	
Case	Distance	Case.	Distance
15	2·6 centimetres	4	7·25 centimetres
7	3 ,,	5	7·5 ,,
2	4 ,,	34	5·5 ,,
27	5 ,,	9	11·5 ,,
16	3 ,,	10	5·5 ,,
30	6·5 ,,	23	10 ,,
22	7 ,,	40	9 ,,
32	7·5 ,,	37	9·25 ,,
11	6·25 ,,	12	8·5 ,,
		31	8 ,,
Average	4·97 centimetres	Average	8·2 centimetres.

The difference between these two averages shows that when the liver is displaced upwards it will leave the kidney to some extent, and, on the contrary, that when the liver is lower than usual it moves down to some extent on the surface of the kidney and diminishes the vertical distance between its upper border in the right lateral line and the upper pole of the kidney. *This conclusion, however, does* not exclude the possibility that the liver in its descent does depress the right kidney in some measure, only in a lesser degree than the liver itself moves downwards We should not have expected that the kidney would have moved downwards as much as the liver, presuming for the moment that it moves downwards at all. We should expect a certain correspondence between the levels of the different viscera in any given case in the absence of exceptional displacing forces *And if we take those cases* in which the right kidney was lowest down we find amongst them a considerable number of cases in which the liver also occupied a low position, and on the other hand, those cases in which the kidney was highest up embrace several in which the liver was also highly situated Before we make any general statement we should notice the position of the duodenum in relation to the right kidney in the cases referred to Now the figures of the duodenum show that in all the foregoing cases of low *livers except three (and in them* to a great extent) the duodenum was almost wholly pushed off the kidney, leaving to that organ a greatly increased hepatic surface (See, for instance, the outline of the duodenum, &c, from Case 24 on Fig 11) On the other hand, the cases of high position of the liver will be seen to be those pre-eminently in which the duodenum passed on to the right kidney near its upper end. The liver, that is *to say*, has displaced the duodenum very much more than the kidney. But many of the cases show much more than this. In Case 16 the upper pole of the kidney was 2·6 centimetres higher than its average both in relation to E, F, and the first lumbar intervertebral disc and nearly the whole of its anterior surface was in contact with the liver, which, with its upper border lower than usual, extended far down into the abdominal cavity. In this case clearly the liver had not displaced the kidney; and it is fairly evident that, so long as the enveloping connective tissue of the kidney remains firm, the liver has little displacing influence on the kidney, if any.

THE KIDNEY AND THE ASCENDING COLON.

The hepatic flexure of the colon must be considered amongst those parts which may contribute to the support of the right kidney, as in most cases it presses considerably on the lower segment of the kidney. If the ascending colon contributes materially to the support of the kidney we should expect to find evidence of it in the cases in which the colon is largely or altogether prolapsed away from the kidney. Cases 2, 7, and 15, and, better still, Case 24 (see Fig. 11) and Case 36 are good examples of this condition. In the two last cases in which the colon had wholly retreated from the kidney, the kidney was even, as it happens, at a higher level than usual. In Case 24 the connective tissue passing from the upper pole of the kidney to the diaphragm was carefully dissected, and it contained a strong fibrous cord which passed on to the right crus. The band evidently gave additional strength to the connective tissue around the kidney. A similar condition was remarked in other cases but in none was it so well marked as in Case 24. In this case also the liver was very low down.

The kidney, apparently in the absence of laxity of its enveloping connective tissue, is very much independent of pressure from the liver above or from the stomach below. The right kidney in Case 11 and Case 38 might be spoken of as moveable; but the cases presented no special feature in other respects.

THE PANCREAS.

The alterations in the level of the pancreas, the relative size of its surfaces, the presence or absence of its omental tuberosity, and the changes in the shape and position of its head have been dealt with under the stomach and the duodenum. As the pancreas passes to the left across the face of the left kidney it frequently presents a slight twist, bringing its inferior surface to look downwards and a little to the right.

THE SPLEEN.

The highest point of the spleen is generally situated just inside the left lateral line 1·1 centimetres below the infrasternal notch. In 25 cases, or 62·5 per cent., it varied from the level of the notch to 2·5 centimetres below it. There were five cases lower than this up to 5·5 centimetres below the notch in Case 27; and there were six cases more than one centimetre above the notch, up to 2·5 centimetres in Case 10. Without going into further details we may say that a high position of the spleen seems to be specially associated with a highly-placed stomach, but that a low position of the spleen does not seem specially to accompany a low position of the stomach. The cases do not appear to establish any direct relationship—apart from a general correspondence of visceral levels—between the level of the spleen and the left kidney.

LEFT SUPRARENAL BODY.

One point should be mentioned in connexion with the left suprarenal body. You will see by the illustrations before you that in many cases the level of the left suprarenal body in regard to the left kidney is greatly determined by the position of the pancreas with regard to the kidney, being nearly lifted off the kidney when the pancreas occupies a high position on the kidney, as in Case 17 and Case 31, or being much depressed in level under opposite circumstances, as in Cases 16, 24, 23, and 36. Although the left suprarenal body follows within certain limits the level of the pancreas in regard to the kidney its variation is very much more limited than that of the pancreas.

THE LEFT KIDNEY.

The upper pole of the left kidney projected in the average one centimetre above the upper border of the pancreas, having thus an average possible gastric surface of one centimetre, and it was situated one centimetre higher and 0·5 centimetre further outwards than the corresponding point of the right kidney. The upper segment of the left kidney, however, usually reached a little nearer the middle line than that of the right. Its lower pole, a little above a point midway between E, F, and C, D, in the left lateral line, averaged four centimetres above the umbilicus and 3·3 centimetres above the highest point of the iliac crest. In 60 per cent. of the cases its upper pole was not more than three-quarters of an inch from the average, and, without analysing the variations, it is a little less variable in its level than that of the right kidney.

Apart from the general correspondence of visceral levels the left kidney does not seem to vary in its level in any regular manner either with the stomach or the spleen. In fact, as in the case of the right kidney, whilst its enveloping connective tissue remains firm, the left kidney seems in a great measure independent of the enlargements or displacements of the viscera in its neighbourhood.

THE TWO KIDNEYS.

In 29 cases, or 72·5 per cent., the upper pole of the right kidney was lower than that of the left kidney; in three cases it was at the same level, and, in eight cases, or 20 per cent., it was higher. It is interesting to notice that three of these last cases (Cases 2, 7, and 27) of high level of the right kidney as compared with the left kidney were amongst those cases of low position of the liver in which the distance between the upper pole of the right kidney and the upper border of the liver in the right lateral line was least, and in which the question was asked whether the liver had simply descended over the right kidney or had in a measure displaced the kidney downwards. The fact that in these cases the upper pole of the right kidney was higher than that of the left strengthens the conclusion already arrived at that the liver in its descent does not as a rule produce any material downward displacement of the right kidney. In 10 cases, or 25 per cent., the lower pole of the right kidney was not more than one centimetre higher or lower than the highest point of the iliac crest. In two of the cases it was below the level of the crest.

Mr. President and gentlemen, we have had to our hand in these lectures a great amount of material. Many things of interest I have passed over without remark; many others I have but lightly touched; whilst others, which it has been my endeavour to present to you, have been taken chiefly because it appeared that they had a more direct bearing on the practice of medicine and surgery, and they, in many cases, have been passed over so rapidly that I am deeply conscious of the reliance I have placed on your generous leniency. I thank you again for the honour you have done me and for your kind attention.

ON THE IMPORTANCE OF EARLY DIAGNOSIS AND TREATMENT IN SURGICAL DISEASES OF THE ABDOMEN.

BY WILLIAM ROSE, M.B., B.S. LOND., F.R.C.S. ENG.,
SENIOR SURGEON, KING'S COLLEGE HOSPITAL.

THE advances which have been made of recent years in the surgery of the abdomen are unquestionable, and it is beyond controversy that many lives are now saved which would formerly have been sacrificed by the lack of operative interference. The general practitioner is in most cases first brought into contact with patients in the earlier stages of their troubles and it depends upon his accurate appreciation of the earlier symptoms, which are often somewhat vague and indefinite, and upon his prompt action whether a successful issue is attained. The insidious and gradual manner in which abdominal symptoms often supervene is calculated to put him off his guard, whilst the frequency of simple functional disorders of digestion with no organic lesion to account for them is likely to lead him to postpone a thorough investigation until a more serious state of things has arisen. It is seldom that surgeons are called in too early, whilst unfortunately we are often summoned too late.

Putting gynæcological questions aside, the chief conditions for which the general surgeon is called upon to open the abdomen may be conveniently divided into two groups, according to whether they arise as the outcome of inflammatory or neoplastic phenomena, and I think it would be well for us to take a few illustrations of each of these groups and compare the condition of affairs in the early and late stages respectively. Turning first to the *inflammatory group* we have, of course, two main divisions to discuss, according to whether the inflammation involves the whole of the peritoneal cavity or is localised. As illustrations of diffuse mischief let us discuss perforation of a gastric ulcer, perforation or rupture of the intestine, and perforative appendicitis.

1. *Perforation of a gastric ulcer* is by no means uncommon. It involves most frequently the anterior wall, and the contents of the stomach pass into the peritoneal cavity, slowly or rapidly, according to circumstances. This predisposition of the anterior wall for perforation is probably due to its greater mobility and to the fact that it is not covered in by other organs to which it can become adherent and thus prevent extravasation. The patient has usually complained of a train of symptoms which point to the stomach as the seat of the mischief. There have been pain after food, repeated vomiting usually coming on soon after a meal, and hæmatemesis, associated with loss of flesh, general malnutrition, and anæmia. It must be admitted, however, that a certain percentage of cases are at first almost devoid of symptoms. The actual perforation may be brought about by traumatism or during an act of vomiting, or, indeed, may be due to some slight abdominal strain of which no notice is taken. The patient complains of acute pain in the epigastrium, followed rapidly by symptoms of shock. The temperature falls, the pulse is weak and rapid, and the face is ashy pale and covered with a cold clammy sweat, which may also extend to the whole surface of the body. The phenomena of acute peritonitis soon follow, and unless surgical assistance is at hand death rapidly ensues. If anything is to be done it is obvious that it must be done quickly, for the longer one leaves the case the more extensive is the diffusion of the septic material and the less the chance of being able to effectively cleanse the peritoneal cavity. It is worth noting in this connexion that the stomach contents are not usually so virulent as those of the intestine, so that operation undertaken within a few hours of the onset of symptoms has a much greater likelihood of being successful. Furthermore, the length of time taken by the operation is less when done early, as the necessity for wholesale washing out of the general peritoneal cavity does not exist, whereas in the later stages it is almost essential to make an additional opening just above the pubes in order to drain and disinfect the lower half of the abdomen.

2. *Rupture of the intestine* is another instance in which time is an all-important element in the question of prognosis after operation. The contents of the intestine, unlike those of the stomach, are excessively virulent, and hence the conflagration set up spreads with the greatest rapidity, so that the time in which a successful operation can be reasonably expected is shorter than in the former. The site of election of intestinal rupture is generally found to lie in the upper part of the jejunum or in the lower portion of the ileum; in the latter the rupture is generally caused by traumatism, such as a kick or a blow in the abdomen during a game of football. The soft and pultaceous material oozes into the general peritoneal cavity, and unless laparotomy is had recourse to within a very few hours death is certain to result.

The diagnosis of these cases is often exceedingly difficult in the early stages, and yet an accurate appreciation of the nature of the injury and of the initial symptoms would irresistibly cause one to draw the conclusion that some serious internal lesion had occurred. For instance, there is the story of a severe blow followed by fainting and general collapse and succeeded by excruciating abdominal pain. Vomiting, increased resistance of the abdominal wall, and a development of general tympanites indicate only too surely the preliminary phenomena of acute peritonitis and if further time is wasted the surgeon's opportunity for a successful interference will be lost. Unfortunately, in this class of abdominal trouble the symptoms follow each other with such rapidity that at present our record of success is nothing to boast of. As time goes on, it may be hoped that increased familiarity with the symptoms will lead to earlier operations and better results.

3. *Perforation of the vermiform appendix* is, we now know, one of the most frequent causes of acute diffuse peritonitis and, indeed, a great majority of those fatal cases which the medical practitioner used to place in the registrar's records as acute peritonitis without any further comment took their origin from this cause. The chief cause of acute perforation of the appendix is the presence within it of some irritating material which usually takes the form of fæcal concretions, containing the bacillus coli communis in large masses. The pressure on the vascular supply to the mucous membrane and other coats results in loss of vitality, bacterial invasion, softening, and perforation. These several processes follow one another with great rapidity, so much so as to earn the name "fulminating" for the attack of inflammation which ensues. It goes without saying that the earlier this condition is realised and properly treated the better for the individual concerned.

The early symptoms are very similar to those of perforative peritonitis elsewhere—viz., shock, pain, and rapidly increasing distension and tenderness of the abdomen. The pain, however, though often at first referred to the umbilical region, soon becomes most marked in the right iliac fossa, and perhaps a point of maximum tenderness may be found at or near McBurney's spot. Vomiting is almost always present and quickly becomes fæcal. The temperature is not necessarily high, since the patient soon becomes poisoned by the toxic products developed in the peritoneal cavity and then collapse ensues. It is also important to note that no definite tumour is to be expected in these fulminating cases, but there is increased resistance to the hand placed on the abdomen, and this is most marked over the right iliac fossa. The association of these phenomena ought to suffice for the establishment of a correct diagnosis and to be quite sufficient to justify the practitioner in insisting on a prompt operation.

Turning now to the more localised forms of inflammatory trouble the same conclusion is constantly forced upon us—viz., that early operative interference is exceedingly desirable, even if not absolutely essential. Take, for example, the less acute types of appendicitis which are likely to terminate in an acute localised abscess. It is admitted on all hands that the primary cause in these cases is an invasion of the walls of the appendix by the bacillus coli communis with or apart from the streptococcus pyogenes. The inflammation thereby lighted up is by no means of such a severe type and therefore there is sufficient time for nature to organise a barrier of adhesions whereby the spread of the mischief may be checked. Should suppuration now take place around the appendix, an abscess forms, the walls of which are composed of coils of intestine agglutinated together by adhesions of variable strength. In this way contamination of the general peritoneal cavity is prevented, providing that the tension within the abscess cavity does not exceed the powers of resistance in the adhesions. Left to itself the abscess may behave in various ways. In the more favourable cases it may burst into the bowel, and indeed there are some authorities who maintain that all the more severe cases which end in recovery take this course; in others the pus may burrow towards the anterior abdominal wall, and point as a subcutaneous abscess; in others a retro-peritoneal abscess is developed, followed by pointing in the loin. In the more serious forms the leakage takes place into the general peritoneal cavity, and if this condition is not soon recognised death from diffuse septic peritonitis is almost certain to ensue. I have in my mind's eye a case of a man, about 30 years of age, to whom I was called in consultation nearly three years ago. He had what I considered all the typical symptoms of acute localised appendicitis. A tense resisting swelling was present in the right ilio-lumbar region, whilst the whole abdomen was distended with flatus and tender. The temperature was above 100° F., the pulse was rapid, and the countenance was expressive of anxiety. He was lying on his back with his legs drawn up and it was obvious that some serious focal point of inflammation existed in the abdomen. The medical attendant (my senior), however, after listening to the opinion given, expressed a firm belief in the efficacy of time and delay. He advised the administration of large doses of opium and that the question of abdominal section should remain over until the following day. When we met over the patient 24 hours after, there were undoubtedly some more favourable signs—that is to say, less pain and less distension. This was doubtless due to the opium, but the medical attendant thought, on the other hand, that it was the result of a general improvement in the severity of the inflammation. It was decided to postpone any active interference for another 24 hours in spite of my having again urged operation without delay. At midnight I was summoned in great haste and on reaching the patient, who was some five miles distant, I found that matters had gone steadily from bad to worse. The abdominal distension was much greater and the symptoms of general septic peritonitis were aggravated all round. Under difficulties which would not have been present in the daytime I proceeded to perform a laparotomy, and as it appeared likely that an extravasation of septic pus had occurred into the general peritoneal cavity I thought it wise to open the abdomen a little nearer the median line than usual. On dividing the abdominal wall and the parietal peritoneum a quantity of stinking pus escaped and on introducing my hand I soon detected the appendix in its usual situation close to the cæcum and free from adhesions. I placed a ligature upon it without difficulty close to the gut and removed the portion below. The appendix was found to be perforated at a small spot about one inch from the apex and it contained a hard fæcal concretion. The abdominal cavity was next washed out with a hot saline solution and the coils of intestine in the immediate neighbourhood of the appendix were thoroughly cleansed. Twelve-inch strips of cyanide gauze about two inches in width wrung out of hot 1 in 40 carbolic solution were placed between and amongst the coils in the region principally affected, and the ends were left projecting some two inches outside the abdomen. The upper and lower angles of the incision were sutured and these so-called lampwick drains were left undisturbed for 48 hours. The condition of the patient was decidedly perilous, but I am glad to say that his constitutional powers proved equal to the occasion and he made a rapid and satisfactory recovery in the course of three or four weeks. Had the operation been performed three days before I firmly believe that we should have found the general peritoneal membrane unaffected and merely a localised abscess around the appendix.

This, however, is not the only danger which may arise from delay in operating in cases of suppurative appendicitis. The veins in the meso-appendix may become thrombosed, and septic emboli be detached therefrom and carried to the liver, giving rise to portal-vein-pyæmia, or diffuse pylephlebitis, as it is termed. Moreover, a general toxæmia may result if even a localised abscess is left too long untreated, and then when finally an operation has to be undertaken to deal with it a fatal issue supervenes from sheer exhaustion. Finally, it is possible that the whole process may become quiescent and a focus of inspissated pus be left in the neighbourhood of the appendix. No harm occurs unless some sudden strain or blow causes rupture of adhesions and dissemination of the pus into the general peritoneal cavity. I have lately met with a case where a gentleman who had suffered from appendicitis some years previously was stooping to pick up his boy's fishing-rod which had fallen into the sea. The timber on which he was standing was wet, and he slipped, and the effort to save himself gave him a slight wrench of the abdomen. He became sick and faint, and after resting a few minutes was conveyed home in great agony and died from acute peritonitis within two days. At the post-mortem examination it was demonstrated that a focus such as we have been just describing had existed for a long time in the neighbourhood of the appendix, which latter was adherent along its whole length.

From a consideration of cases such as these, which, be it noted, are by no means uncommon in surgical practice, there is no question that the surgeon is inclined to recommend operative treatment at a much earlier date and much more frequently than our medical *confrères* are willing to agree to. Let it be granted that there is a class of mild cases of appendicitis which will get well with more or less rapidity if only the patient is kept quiet in bed, his diet restricted to fluids, and a certain amount of opium administered. But even in such, where the proportion of recoveries is claimed to be about 90 per cent., physicians have to admit that recurrence is likely to take place in at least 30 per cent. of the cases—and remember, these recurrent attacks need not be of the same mild type as the first, and as a result of any of them the patient may rapidly pass into a condition of grave risk. Again, we must not forget that although an attack may commence with apparently mild symptoms one never knows when more acute phenomena may supervene and place the unfortunate patient beyond the help of surgery. Under these circumstances one is forcibly driven to the opinion that surgical interference ought to be undertaken much more frequently and much earlier than it is, and although we may not be willing to agree with the practice followed by some American surgeons—viz., to operate immediately the condition is diagnosed—yet one would be glad to see more active and energetic methods of treatment introduced in this country. When undertaken early the bacterial invasion has rarely spread very far, and with the ordinary precautions that we are in the habit of adopting there is no reason why an operation should not arrest further dissemination.

Turning now to the *neoplasms of the abdominal viscera*, the different possibilities that present themselves according to whether the disease is recognised early or late must be traced out.

Cancer of the stomach manifests itself in a number of different types. When the cardiac orifice is involved the chief symptoms are inability to complete the act of deglutition and the regurgitation of food at a variable time after its ingestion according to the amount of dilatation of the œsophagus which has taken place; as a general rule, the food is retained for a few minutes or even perhaps half an hour, but its retention is accompanied by pain which the patient usually refers to the middle of the back about the eighth dorsal vertebra. Unfortunately, there is no possible means of dealing radically with this affection and yet there is an important point to note in connexion with our subject—viz., that the only operation which can in any way alleviate the symptoms—that is, gastrostomy—must not be left till too late. Undertaken early it gives a very appreciable amount of relief to the patient, and I have even known of cases where the patient put on weight afterwards and lived for 12 months; in some the power of normal deglutition returned in measure and thus the patient was able to take in nutriment in two different directions. Generally, however, these patients are sent to us for operation only when all power of deglutition has disappeared, or at any rate when they can only with difficulty swallow fluids; they are in a miserably emaciated condition, and the operation of gastrostomy is a severe tax to their powers, and hence the death-rate is high and the amount of relief given very slight.

There are two chief ways in which cancer attacks the body of the stomach—viz., it is either a localised nodular growth or a generalised infiltration, the latter being the more common. In the former type the growth, which is a columnar carcinoma, constitutes a hard tumour of slow development, which unfortunately gives rise to but few symptoms. The organ is not enlarged; there is no stenosis of the orifices; vomiting is slight and has but little relation to food; and hæmatemesis is often absent. The patient complains of pain somewhere in the region of the stomach, the site varying with the position of the ulcer, and a lump may be felt if the growth is on the anterior wall. Steady loss of weight will be an important symptom. In the diffuse type of cancer of the stomach the organ becomes much contracted, and in one case recently reported by Dr. Bryant in the *Clinical Journal* the organ, which normally can hold three pints of liquid, could only retain two ounces. The walls of the organ are thick and hard, constituting a solid mass which can frequently be detected by palpation in the epigastric and left hypochondriac regions. Vomiting is an invariable sequence of this affection and usually follows the ingestion of food within half an hour; there is little or no hæmatemesis since the mucous membrane is intact and free from ulceration.

In either of these conditions lymphatic troubles soon follow, the glands lying above and below in the lesser and greater omenta first becoming involved; subsequently those lying in the portal fissure become also affected and these may lead to ascites or jaundice from pressure on the portal vein or bile-duct. Locally the growth may contract adhesions to surrounding viscera or may extend into the substance of the great omentum, which may develop into an enormous mass of cancerous disease and perhaps undergo colloid degeneration. It is obvious that early diagnosis makes all the difference in the world in the result of such cases, and that failing the establishment of this diagnosis the patient must inevitably and quickly succumb. The very fact that a diagnosis is a matter of difficulty emphasises the statement that should a patient present himself with a story of persistent vomiting which medicines are unable to control, together with fixed pain in the region of the stomach and perhaps a feeling of resistance in the epigastrium, even though no actual tumour can be felt, and still more if there be some history of preceding hæmatemesis—then under these circumstances it would be perfectly justifiable to propose and to execute an exploratory laparotomy with a view of settling the question as to the existence or not of malignant disease, and then it may be possible to effect a cure And here let me state very emphatically that whilst early operations on the stomach hold out considerable prospects of cure, if the disease is allowed to invade the whole organ they become matters of the greatest gravity and in many cases the abdomen has to be closed and the unfortunate patient relegated to his unhappy fate without hope of relief or cure Let me lay before you a few facts as to the present position of the operative treatment of malignant disease of the stomach which I have gathered from the second edition of Mr H T Butlin's valuable work on "The Operative Surgery of Malignant Disease"

Operations for excision of cancer of the stomach are of comparatively recent introduction, but already a considerable mass of information is obtainable Excision of the whole stomach or of the greater portion of it has been undertaken in 14 cases with five deaths and in all of the fatal cases the cause was shock and not sepsis Partial gastrectomy for malignant disease is a very unusual proceeding, as so few cases are met with in which it can be usefully practised; there cannot be the slightest doubt that were it adopted in suitable early cases a large measure of immediate success would accompany it

As to the question of final cure after these proceedings the following facts may be mentioned Porges removed nearly all the stomach for cancer and the patient was alive and well six years afterwards In Schlatter's well known case of total gastrectomy the woman died from secondary cancerous deposits one year and two months later, but there had been no local recurrence Schuchardt's patient had all the stomach removed except a strip near the cardiac extremity, she died from cancerous pleurisy three years later, whilst the portion of stomach left to her had dilated sufficiently to allow of the introduction of 500 cubic centimetres of food Most of the other cases are too recent to be of any statistical value Ricord has lately recorded a case[1] in which he removed the whole stomach, the first part of the duodenum, and a considerable portion of the pancreas which was infiltrated by the cancerous growth, and the patient was alive and well 11 months later

Cancer of the pylorus usually gives rise to a much more definite and characteristic group of symptoms It is a hard cancer of the *scirrhous type and therefore* develops slowly, and thus allows a margin of time in which curative operations may possibly be undertaken with success The growth limits itself in a curious fashion towards the duodenum, but spreads freely into the adjacent portion of the stomach It tends to involve the whole of the pyloric orifice, and thus stenosis is usually produced before the growth has lasted very long Dyspepsia of a gastric type—i.e., pain after food, especially if it be of an indigestible character—a
vomiting will be the earliest
before long the symptoms of
every two or three days the
quantity of semi digested fo
undergoing fermentation, as indicated by the existence on the top of a frothy scum Any lump that forms is to be *detected on the right of the* median line, and partly owing to the weight of the mass, partly to the dilatation of the stomach, this will be felt below the normal position of the pylorus—i e, not far from the umbilicus In the earlier stages this growth is moveable and free from adhesions, whilst lymphatic complications are not very rapid in their development. It is thus obvious that granted a diagnosis before fixation of the neoplasm by adhesions or before such lymphatic developments, there is a *prima facie* probability that removal may be successfully accomplished The *operation of pylorectomy* was, however, at one time looked upon as such a dangerous proceeding as to almost put it out of the pale of justifiable operations, thus Mr Barker states that a mortality of 76 5 per cent was connected with it during the eight years between 1882 and 1890 Fortunately, our methods have so improved of late that the same authority states that the death-rate during the years 1890 to 1898 had been reduced to 28 6 per cent, whilst individual operators could claim even better results from their work Thus Kronlein lost only two out of his last 20 cases, and
last 10 As to the ultimate
Haberkant has collected 51
after history are known: 26 of the patients died within from one to six years, 23 dying within two years; 21 were alive and well at periods varying from one to eight years after the operation; four were alive and well beyond the three year limit, and four were alive with recurrence. Kronlein and Mikulicz have operated on 35 cases in all, six were fatal directly as the result of the operation, 16 occurred after operation, two patients died within a year, but not from the cancerous disease, two were well within from one year to two years of the operation; and two only were alive after four years Fr
that although up to the present
been finally saved from the clu
that is mainly to be attribute
diagnosis and consequent treatr
is finally fatal the patient is much more comfortable after operation than before, and all the accounts go to prove that local recurrence is infrequent

Should pylorectomy be impracticable owing to the extent of the disease, all that the surgeon can do for his patient is to perform a gastro-enterostomy which has a death rate of at least 10 per cent attached to it, and which at the best can only give relief for a few weeks or months It is obvious how very important the question of early diagnosis becomes in such a disease as this, and that in cases of doubt there should be no hesitation in the general practitioner suggesting expert advice and the performance of an exploratory operation

Passing now to the subject of *intestinal cancer* one has in the first case to note the extremely insidious character of its onset, although the affection itself is to be looked on as less malignant than cancer in other parts of the body Frequently there is very little indication of its presence until stenosis of the intestine has progressed to such an extent as to lead to obstructive phenomena, whilst the appearance of a lump is often delayed to a period when the disease has gained such a foothold in the patient as to render all attempts to extirpate it nugatory Progressive wasting and recurrent attacks of paroxysmal pain with irregularity of the bowels (usually consisting of periods of constipation followed by diarrhœa) are the only early phenomena which suggest its presence. It must also be noted that the large gut is much more frequently attacked by this affection than is the small gut

As to the results of operative interference statistics do not give very favourable figures I shall only take
growth could be at once
is to say, one has to
disease when obstruction existed and a temporary or permanent opening had to be established The immediate death rate connected with this operation is about 35 per cent Lardennois, who has laboriously investigated this matter, gives the following figures —

—	Cases.	Deaths.	Mortality.
Removal of the cæcum and ascending colon	79	28	35 4 per cent.
Removal of the transverse colon	66	25	37 8 „
Removal of the sigmoid flexure ..	36	12	33 3 „

The question of actual cure must at present be admitted to be in an uncertain condition, since the better and safer methods of enterectomy have only been recently introduced Von Bramann relates 14 cases six patients died directly as the result of the operation; there was one recurrence, *three were alive less than three years afterwards,* and four were alive more than three years afterwards Czerny has performed 18 such operations with nine deaths and three recurrences. Three patients were alive less than three years, and three were alive more than three years after operation. The conclusion that is irresistibly drawn from these figures is that in spite of the extensive nature of the lesion in many of the cases *there has been a very gratifying* degree of success, although one cannot but admit that the mortality has been high, whilst one is also justified in believing that had many of these operations been performed at an earlier date the results would have been much more satisfactory Three chief causes of death have been alluded to—viz, shock, sepsis, and recurrence Early operation, by lessening the magnitude of the proceeding and consequently by diminishing the time occupied, would lessen shock. The better condition of the patient's general health and nutritive state would increase his germicidal powers and minimise the risks of sepsis which would then mainly depend on errors in the operative technique which should be easily avoidable. Lastly, it goes without saying that the earlier the operation, the less the likelihood of recurrence.

---

[1] Gazette des Hopitaux, March 22nd, 1900.

Space does not permit me to discuss many other surgical affections of the abdomen in which the same conclusions might be drawn as to the serious consequences which are likely to ensue from a *laissez-faire* course of action until the diagnosis is made obvious by complications which render curative treatment impracticable.

In emphasising the importance of making an early diagnosis it may be useful to pass in review the salient features and the chief signs and symptoms which should be looked for as soon as the practitioner is called to the case. In the first place, it is usually possible to get some general idea as to the particular region affected or as to the probable nature of the case from a consideration of the more prominent symptoms present and the method of onset of the attack. Thus an old-standing history of repeated vomiting, perhaps associated with epigastric pain, suggests the stomach as the site of the lesion. An attack which commences suddenly with abdominal pain and vomiting suggests an acute inflammatory lesion, or possibly perforation or strangulation; then, if the temperature is high, the former of these lesions is the more likely, whilst a normal or subnormal temperature is indicative of the latter. Then, too, the localisation of the pain may be suggestive—e.g., pain in the right iliac fossa leads one to suspect appendicitis, although in this affection it is often referred in the first place to the umbilicus. The greatest difficulty will always be experienced in those cases where the symptoms are from the first vague and indefinite and the onset is very gradual. The age and sex of the patient will also have an influential bearing in forming an opinion. Thus, malignant disease of the abdominal viscera is unusual before the age of 40 years, although sarcoma of the kidney, and occasionally of the intestine, is seen in the first decade of life. Inflammatory diseases are more common before the age of 40 years. In children acute abdominal mischief is probably due to intussusception or appendicitis, whilst more chronic affections suggest tuberculous peritonitis or a similar disease of the mesenteric glands. It is also useful to note that appendicitis is more frequent in men than in women in the proportion of about four to one; gastric ulcer is infinitely more prevalent in the female sex, whilst ovarian and tube lesions should not be overlooked. The previous medical history of the patient may throw light upon the case. Thus one or more attacks of prolonged vomiting after food together with hæmatemesis would suggest some of the sequelæ of gastric ulcer, such as stenosis of the pylorus. An earlier attack of dysentery may be the cause of stricture of the rectum or sigmoid colon. Prolonged diarrhœa and abdominal pain in a patient with a tuberculous history would suggest the possible existence at an earlier date of tuberculous ulceration of the bowel, and this may result in stricture, usually of the small intestine. A former history of severe colicky pain in the right hypochondrium, followed by jaundice or at least by an icteric tinge about the conjunctivæ, would lead one to suspect some of the sequelæ or complications which arise from gall-stones. Previous attacks of pain in the right iliac fossa together with vomiting would make one suspicious of some chronic trouble in connexion with the vermiform appendix, whilst if the pain were lower down in the pelvis, and especially if associated with backache and aggravated at the menstrual periods, ovarian or tube disease would be thought of. Persistent loss of weight is, of course, an important and suggestive phenomenon, frequently pointing to malignant disease, but one must not allow this symptom undue importance, as it may be due to simple malnutrition from functional causes connected with chronic dyspepsia. It is also well to find out the occupation of the individual and to inquire into his habits of life, as some useful information may be thereby obtained. It is only necessary to mention the association of intestinal colic with lead-poisoning in plumbers and house-painters to illustrate the force of this remark, whilst an alcoholic history may explain a hæmatemesis which would otherwise suggest ulceration of the stomach.

We must not, however, allow ourselves to be unduly biased by these symptoms or carried away by these considerations, important though they may be, without bringing forward either in support or opposition every fact that can be elicited by physical examination of the patient and of the abdomen. In the first place, one may learn a good deal from a careful notice of the general aspect and facies of the individual. A placid, calm expression of the face usually indicates that there is no mischief of an acute, active, or urgent character present in the abdomen, for when such mischief exists there is a pained, drawn, and anxious look, the face being pinched and pallid, whilst in conditions of acute obstruction or strangulation the forehead may be covered with a cold, clammy sweat. Again, a hectic flush on the cheeks would suggest some chronic toxæmic condition, and granting that the mischief is limited to the abdomen one would naturally think of tuberculous peritonitis. A yellowish tinge of the face would in like manner lead one to suspect the liver as the cause of the trouble. In the next place we should notice the decubitus, as to whether or not the patient always lies on his back, and if so whether the legs are drawn up as in peritonitis; possibly in appendicitis only the right leg would be thus flexed.

Having obtained all the evidence possible by such observations as these we come to the actual examination of the abdomen, and in order that it may be thorough and exhaustive (as it should be even in apparently trivial cases) it is essential that the whole abdomen should be bared and exposed to view, whilst when one commences to palpate the knees should be drawn up so as to relax the abdominal muscles. To commence with, the practitioner should notice the general contour and condition, whether there is any general or localised distension or flaccidity, and if the former where it is located. Central distension frequently indicates an ovarian tumour, a distended bladder, or obstruction to the small intestine, whilst bulging of the flanks is significant of a dilated colon or of dropsy. The appearance of an abnormal projection of a limited portion of the abdominal wall suggestive of the presence of a tumour can sometimes be observed. A swelling located in the epigastric and left hypochondriac regions suggests a tumour of the stomach; a pyloric tumour usually presents a little to the right of the umbilicus and just above it; a distended gall-bladder can often be seen during the movements of respiration below the costal margin in the right hypochondrium; whilst a projection in the right iliac and lumbar regions may possibly be due to an abscess round the appendix or to malignant disease of the cæcum; an obvious enlargement in the left lumbar region may be due to either spleen or kidney. Dilated coils of intestine can sometimes be seen, and when this is the case it is not unusual to be able to see them traversed by a wave of peristalsis; such a condition is indicative of chronic obstruction due to some narrowing of the intestine, either simple or malignant. Then again we must note the character of the respiratory movements and how far the abdomen participates in the process. In almost all acute peritoneal lesions thoracic respiration is alone utilised. Where there is an obvious tumour the influence of the respiratory act upon it must also be noted, since it is only in those which are more or less directly connected with the diaphragm that downward displacement occurs during inspiration. Of course, any localised area of redness, particularly if this spot is œdematous, would suggest that an abscess is travelling towards the surface.

Having learnt all that is possible by simple inspection we should next proceed to palpate the abdomen, and in doing so we should endeavour to get the abdominal muscles relaxed as much as possible. To this end not only should the patient's knees be raised, but his mouth should be open and he should be told to breathe in and out quietly and regularly. The examiner's hands should be warm and care should be taken not to suddenly drive one's fingers into the patient's abdomen, but the flat of each hand should be gently placed on it and the pressure gradually increased. The tension of the abdominal parietes should first be observed and, supposing there is a sense of resistance, whether it is general or local. Next it should be ascertained whether marked tenderness exists, and if so an effort should be made to localise the point where it is greatest, whether in the epigastrium, as in cases of perforated gastric ulcer, or in the iliac fossa, as in appendicitis, or elsewhere. In chronic cases careful examination for a tumour should be made and if one should be found it would be important to ascertain by this means whether it is moveable or fixed; whether the respiratory movements influence its position; whether it is solid or fluid; whether it is smooth in outline or nodulated; and if possible to determine with what viscus it is connected. To this end a bimanual examination is sometimes useful, the second hand or some part of it being placed either behind the loin, as in suspected renal tumours, or in the rectum or vagina if there is any suspicion of its being connected with the pelvic viscera. Percussion is another valuable agent in the examination of abdominal swellings, although it must be admitted that the mobility of the small intestine and its ready displacement may lead to an incorrect interpretation of facts. In particular it may *be mentioned here that tumours of the kidney* are always dull in the flanks, but even when of large size a line of resonance may be detected running longitudinally over them in front, due to the presence of the colon. Splenic enlargements or a dilated gall-bladder, on the other hand, will follow the anterior abdominal wall, and it is rare for intestine to be found in front of them.

In addition to this routine method of examination special and confirmatory evidence may be derived in investigating the lesions of particular regions. Thus in affections of the stomach it is often desirable to ascertain the character of the gastric secretion, the capacity of the viscus, and whether or not its contents are passed onwards in the usual time. To investigate the first of these it is necessary to give the patient a test meal and then remove the contents of the stomach for chemical analysis about an hour afterwards. The meal consists of a cup of weak tea without much milk and a thin slice of toast administered the first thing in the morning on presumably an empty stomach. The chief point required in *the analysis is the amount and character of the* acid secreted, since in carcinoma the percentage of hydrochloric acid is usually very much diminished, whereas in other conditions it may be increased. In the same way by the introduction of a tube the capacity of the organ can be ascertained.

Accessory means of diagnosis at our command in connexion with affections of the intestines are unfortunately very limited; and I may mention here the fact that examination under an anæsthetic, though often utilised, is not of much real value, since in the early stages a tumour or other affection is usually so small that it cannot possibly be detected even in a thin person, whilst the addition of a thick layer of subcutaneous fat still further adds to the [illegible] bowel, or where disease is suspected, it is always desirable to make a careful rectal examination, whilst in females an examination per vaginam may also be employed. Thus in appendicitis a tender spot may sometimes be found high up in the bowel on the right side, especially in those cases where the appendix is directed downwards and *backwards,* under which circumstances an abscess connected with it tends to travel towards the pelvis; in many such cases, although the abdomen may be generally distended, there is no lump to be felt in the iliac fossa and no tenderness. Again, a rectal examination must form part of the routine method of investigating any and every case of intestinal obstruction. Surgeons have been constantly called in to cases of this nature where, had this precaution been previously taken, the necessity for their being summoned would not have arisen. Large masses of fæcal accumulation have been the sole cause of the trouble, and the administration of a few enemata and the removal of scybala if need be, by a suitable spoon, will clear up the case. I recollect being called down into the country to a case of intractable anal fistula which had been slit up in the usual manner nearly two months previously. Iron had been freely administered as a tonic, but the wound would not heal. On inquiring as to the state of the bowels I was informed that there was a constant diarrhœa present. On exploring the rectum with the finger I found a large hard fæcal [illegible] foreign body was followed in the course of a short time by the healing of the wound. Once more it must not be forgotten than in children a rectal examination in cases of obstruction *may reveal the existence* of an intussusception, although we may hope that a diagnosis would be made long before the apex of the intussusception had reached the rectum.

Assistance in diagnosis is often derived from the passage of a catheter or sound into the bladder, and the use of the former has in many cases resulted in the rapid disappearance of what had previously been supposed to be an abdominal tumour.

The radiographic process unfortunately does not help us much in the investigation of abdominal cases. It may be useful to locate a foreign body which has been swallowed, or a bullet, and in some very thin persons a stone in the kidney has been detected, or a Murphy's button in the intestine. The resulting photographs are generally so indistinct as to be of no practical value, but it is quite possible that this process may be improved upon.

Having thus exhausted all possible means of investigating *the case, one may hope that some tolerably clear idea as to* the nature of the lesion has been arrived at, even if an actual diagnosis cannot be given. Of course, we cannot close our eyes to the fact that functional troubles occasionally arise with a group of symptoms so like those produced by organic disease that it is almost impossible to differentiate between the two apart from an exploratory incision. Thus in the aged the functional activity of the various abdominal viscera is often much diminished, giving rise to phenomena very like those of actual disease—e.g., a loss of tone of the intestinal wall may cause marked constipation, flatulence, and even obstruction, or a similar condition of the stomach may lead to dilatation of that viscus suggestive of pyloric stenosis. It is abundantly clear that the symptoms of organic disease and functional trouble overlap, and therefore in a certain number of abdominal cases the diagnosis will always remain indefinite. In such circumstances the patient should be told the facts, the advantages and risks of an exploratory operation should be pointed out, and the *decision should be left to him or her,* or in the case of the young to those in responsible charge.

Harley-street, W.

POST-PARTUM HÆMORRHAGE.[1]

BY E. STANMORE BISHOP, F.R.C.S. ENG.

I WELCOME this opportunity of bringing before you a subject which is interesting and important to all medical men—doubly important, I conceive, because when a case illustrating it occurs to them they find themselves suddenly, almost without warning, in the presence of a crisis in their lives. Immediately they must decide upon their course of action—there is but little time for careful consideration, seldom time enough for consultation with others, never for recourse to books. There and then they must act; and upon their action depends the life of one person certainly, probably *of two,* and the happiness or misery of the family whose whole reliance, whose whole trust rests on their shoulders. When this crisis arrives there is no place for discussion. Each man must go into the fight with a clear cut idea in his own mind of what he has to do, why he has to do it, and how it should be done, and upon the truth or otherwise of his idea will depend the result. Is it not well, therefore, that now, whilst we can coolly and calmly do it, we should examine our ideas and make certain that they are correct, so that when that crisis arrives, as it is almost certain to do with each one of us, there may be no doubt, no hesitancy, *no fear* in our action?

The necessity for some definite utterance on this subject has been emphasised by the debate which took place last year at the meeting of the British Medical Association at Ipswich. It was there demonstrated that the ideas as to treatment expressed by those representatives of obstetrical *science* who were then present are still the same as those to be found in all manuals on obstetrics for the last 40 years. Professor J. W. Byers who opened the discussion, Dr. R. Boxall who represented the intended introducer, Dr. W. R. Dakin, the President, almost everyone who spoke, showed plainly that the same fundamental ideas were present in all their minds and influenced all their advice. That ideas are old is, of course, nothing against them. If they are true time can but more thoroughly demonstrate their truth. If they are true time will not only do that, but it will eliminate every particle of doubt as to their application in any given case—will enable their holders to act definitely and with confidence, knowing that their confidence will be justified by the result. Conversely, if the teachers and holders of certain ideas speak as vaguely and tentatively now as to practice as they did 20 years ago, it is at least suggestive of the unreliability of the governing principles which they hold.

---

[1] A paper read at the opening of a discussion at the Clinical Society of Manchester on March 20th, 1901.

Now, the duty of the opener of a discussion, as I understand it, is usually to place before the members present all the points in the subject in question *seriatim*, dealing with etiology, symptoms, pathology, treatment, prognosis, in direct order, being chiefly careful to omit nothing and expressing no very strong or decided opinion himself, but leaving the whole question open for those who are to follow. After what I have said, however, you will probably not be surprised if I depart somewhat from that method to night—so admirable in the majority of cases—because I fear that the result would not be that at which I am aiming.

Permit me, as a preliminary, to sketch as briefly as possible a case of this kind. Those of you who have encountered a really severe case will, I think, agree as to its fidelity to truth; those who have not will perhaps more clearly realise thereby the various points which I wish to emphasise. You have attended what has appeared to be an ordinary confinement—ordinary in every way probably, though sometimes certain things may have been noticed which differed from the typical condition. It may have been a primipara, and the young mother has welcomed with intense delight the new interest in life which has just been shown to her. The memory of previous pain is obliterated at once by the touch of the tiny fingers. She is happier than she has ever been and is looking forward to the blissful days in store for her with her little one to care for, to pet, and to be proud of. The young father has half wrung your hand off in his feeling of intense joy and gratitude to you for your skilful management of what to him is still the severest and most amazing operation of modern times, when the nurse mentions casually to you that there is rather more "loss" than she thinks there should be. You look at the napkin she holds out for your inspection. It is soaked with blood. You raise the bedclothes to inspect. The lower sheet is soaked as well and blood is gushing out of the vulva. The patient's face is paler, too, and her pulse is thin and rapid. You feel for the uterus, which a few moments ago you had left hard and firm above the pubes. Where is it? There is nothing here but a soft, rather full, pulpy sensation, which may be intestine or a totally relaxed uterus. Feeling about you detect a faint outline of what may be that organ. Compressing this you note with delight that it sensibly becomes firmer under your pressure. Continuing along its line, gradually more and more of the surface becomes palpable, firm, and resistant. You seek further still and in order to compress the new portion you relax your grip upon that which you at first held; that is firm, it will surely remain so whilst you attend to the rest. You succeed with the latter part, and bringing it down to the level of the first you pretty confidently pass your hand to the point at which you left that, but it is no longer there: it is where you found it at first and as flabby as ever. Calling the nurse you place the part which you have contracted in her hands, telling her to hold it fast, whilst you once more search for and compress your original portion. Having succeeded to some extent, but not so completely as at first, you tell her to remove her hand, so that you may compress the two together. That in its turn is gone, the nurse does not know how, "It just slipped away," and you can feel that the part you yourself are holding is just "slipping away" too. Meanwhile the flow of blood from the vagina has not decreased. It is if anything freer and more copious. The anxiety now written on your face and your efforts have not escaped the eyes of your patient, or of her husband. Her own rapidly-increasing weakness has made her irritable and nervous. "What is the matter, doctor?" comes from both. "Am I going to die?" is added by the patient. By an effort you control yourself. "Die!, nonsense," you say. "There is rather more bleeding than there should be, but we'll soon put that right. You just lie quiet while we get this stopped." "And you," to the husband, "had better go downstairs for a while. We'll call you up again as soon as we can." The husband departs, half satisfied. The wife, with "Oh, I do feel so ill," tries to be quiet. You get your hypodermic case and inject strychnine and ergotine; whilst the nurse gives the patient some brandy. Once more you try to force that sluggish uterus to contract by firm kneading of the abdomen. Once more the same half result, exciting your hopes at one moment, only to dash them to the ground at the next. "Send someone round to Dr. Jones," you say to the nurse; "tell him I should be very much obliged if he would come here." "Now," to the patient, "don't be alarmed, but we shall have to try something that requires two men, that is all." You get your bottle of ergot and give her a teaspoonful. "Oh, doctor, that *is* nasty, oh! oh! I'm going to be sick," and up comes your ergot again, with the brandy she had previously taken. You keep your hand on the uterus—or rather on the place where the uterus may be supposed to be, for you cannot feel it—whilst she vomits, but in spite of your pressure blood continues to flow as freely as ever. "Nurse, have you any very hot water?" By great good luck, which is not always to be depended on, she has plenty. By the same good luck the man you believe in most walks in at the same moment. "Good," you say, "now we shall do. Jones, this is 'p.p.h.' Just help me, will you? I am going to inject hot water." "Right," says he, pulling off his coat, "just let me sterilise my hands." "Oh, don't wait for that," you say, "she's pretty bad." By this time the patient is beginning to toss about and gasp slightly as if for breath. However, you get her into position and pull down the uterus with a vulsellum; the bleeding is still free, but a little checked. You pass in a long tube right up to where the fundus should be and pump in your hot water. A number of clots are washed out and the amount of blood following appears to be decidedly less. More and more hot water is used and at last it returns almost clear. "That's done it," you say; "now we shall be all right. Don't be afraid, Mrs. Smith, you're all safe now." "Oh, doctor, what is the matter, oh, I *am* ill. I'm going to be sick again." "Try not to, Mrs. Smith—here, suck this ice, that will stop it." For two or three minutes she is quiet, but her breathing is very short and quick, then she begins to be restless again, and suddenly vomits. As she does so you see the red gush of blood from the vulva once more. "What had we better do, Jones? you see she has spoilt it all by that vomiting." "Better use the hot water again, it stopped it splendidly the last time." So you repeat the performance whilst Jones squeezes the abdomen with all his force. This time the hot water certainly checks the bleeding, but not so completely. This may be due to the increasing restlessness of the patient who can with difficulty now be induced to be still enough to allow you to do what is necessary—you fear that your tube perhaps did not reach the fundus, though you passed it as far as before or further. But Dr. Jones reminds you that some clots or a bit of placenta may not be dislodged, and we are all taught that the presence of a clot or of a fragment of afterbirth acting as a foreign body may perpetuate the bleeding; so you pass in your hand and find it apparently in the abdominal cavity, for no boundary can you feel. The only thing which calms your anxious mind—now extremely anxious, not to say nervous, since the bleeding is freer than ever and the patient's lips and eyes are white—is the fact that you feel no intestine; otherwise you would be apt to fancy that the uterus had ruptured and your hand had passed through the rent. You bring out a few clots and pass your hand in once more. Apparently there are just as many clots as before. "This won't do, Jones." "Have you any ice?" to the nurse. Yes she has some, and you inject ice-cold water. Again a check for a few moments. "Inject some more strychnine and ergotin, will you, Jones?" Jones does so, and looks very gravely as he inspects the pulse, conjunctivæ, &c. "She's very bad," says he, "I think you had better pack her. I have some iodoform gauze," and he produces a six-yard packet. You forcibly pull down the uterus with vulsellum forceps and clean the vagina, which you can easily do, for, curiously enough, as soon as you apply firm traction the worst of the bleeding abates. Note this fact, for I wish to call your attention to it later. Very carefully and methodically you clear out the clots from the interior of the uterus and proceed to pack in the gauze. You pack it all in, every bit, and you feel happy, for during the process no bleeding of any consequence has occurred, and you take off your vulsella and allow the os to reascend. But a glance at the patient's face makes you uneasy again; the pulse, too, is very quick and thin; this, however, may be only the natural result of the blood already lost. Jones puts his hand on the abdomen. There is no firmly contracted uterus to be felt—merely an increased fulness where the gauze lies. "Are you sure," says he, "that you packed the uterus itself?" "My dear fellow," you reply, "I put in enough to make her a ball-dress, and I will swear that it went into the uterus. Shall we pack in some more?" "Well," says he, "I don't like her looks. She looks very much to me as if there were some concealed hæmorrhage Her pulse, too, is very rapid It hasn't made the uterus contract at all, and, for anything we know, she may just be bleeding away as fast as ever, and it wouldn't show until too late I think, don't you? that we had better have it out again and use the injection of iron Besides, after all, it is a foreign body, and you know foreign bodies in the uterus, if they don't make it contract, set up acute dilatation, and we shall be worse off than before Better use the iron, that is our 'last resource' and surely we are justified now in trying it Barnes says it is very effectual" So you set to work and pull it all out again, which takes a little time, but Jones is justified, for as soon as you unplug the cervix out comes once more a perfect rush of blood and clots The patient is tossing wildly now, trying to sit up, gasping for breath. "Oh, doctor, doctor, am I going?" and then she vomits again "Oh, nurse, oh, my poor little child I'm dying, I'm dying Send for my husband," and all the rest

which

o take

ection

to be

used when evrything else has failed, as in some cases it has directly killed the patient With increasing difficulty, owing to the increasing restlessness, you get your tube in once more and pump in the iron God be thanked the bleeding stops, the whole discharges are blackened, and the flow ceases; but whilst you are congratulating one another a thin, bright red line trickles out once more over the black surface, becoming freer, fuller, brighter You pump in more iron solution, same result Hope for

ment, almost despair, the next

become strangely still and Jone

her face and he seizes her wrist "By Jove, she's going," says he, and rushes for brandy A teaspoonful of this he tries to get her to swallow. The spoon rattles against the clenched teeth, the brandy runs down her face, and with a few long-drawn sighs, with wide open eyes and dilated pupils fixed on you, it seems to you reproachfully, she is dead

I pass over, though you will not, the sudden wretched desolation of the husband, so much the more poignant because so unexpected, the interview with whom will be one of the saddest you will ever have to face

I said that our dying patient looked reproachful, and no one who has been through such a scene but will understand why we should fancy so, and how her look will haunt us for days whilst we go over and over again all that has happened, and ask ourselves everlastingly, "What more could we have done? and why did not our measures succeed?" In the case which I have supposed everything appeared to be in our favour We had a young healthy woman, our friendly medical brother appeared as soon as wanted; everything was at hand and had not to be waited for Had things been otherwise, as they usually are, we might have blamed the lost time, but that is here impossible and yet we failed Why?

Now you will notice, if you look back, that all our efforts were directed to two definite things We had two definite aims—viz, first to obtain and,

secondly, in our last effort, the

blood in addition Well, ities

lay stress upon the absolute necessity of obtaining uterine contraction at any cost As to this point, which is all important to my argument I had prepared numerous extracts from Playfair, Galabin, Dakin, and Jellett, all of them text books in use at the present moment in the various medical schools; but it was soon evident that I should only weary you if I attempted to read them all One, however, I venture to give you, somewhat condensed, it is true, but merely omitting non essentials For the rest I confidently appeal to

used, and it is only in the worst cases, in which they have been assiduously tried and have failed, that we resort to those coming under the second heading" And Galabin says; "The essential point in treatment is to secure contraction of the uterus" Playfair continues. "If the uterus be found relaxed and full of clots, by firmly grasping it in the hand contraction may be evoked, its contents expelled, and further hæmorrhage at once arrested. Another method of applying uterine pressure has been strongly advocated by Dr Hamilton It consists in passing the fingers of the right *hand high up into the posterior cul de sac of the vagina*, whilst counter pressure is exercised by the left hand through the abdomen During the time that pressure is being applied a full dose of ergot should be administered, and if one has already been given it should be repeated We cannot, however, look upon ergot as anything but a useful accessory, and it is one which requires considerable time to operate" (and the time at our disposal is to be measured by minutes, not by hours) "Hypodermic ergotine offers the double advantage in severe cases of acting with greater power and much more rapidly It should, therefore, always be used in preference" Then he mentions brandy in order to warn you against making the patient drunk; and hypodermic injections of sulphuric ether when exhaustion is very great "Open the window, remove the pillows, keep the head low, and 'assiduously' fan the patient It is often found to be useful to raise the feet of the bed on blocks of wood or books, so as to have the head lower than the pelvis This will favour the current of blood to the head and lessen the tendency to syncope *If bleeding continue* the hand should be carefully and gently passed into the uterus and its cavity cleared of its contents The mere presence of the hand within the uterus is a powerful inciter of uterine action When the placenta is retained it is the more essential as the hæmorrhage cannot be checked as long as the uterus is distended by it, Various means are used for exciting uterine contraction by reflex stimulation Among the most important of these is cold but to be of use it must be used intermittently and not continuously Ice can generally be obtained, and a piece should be introduced into the uterus. A large piece of ice may also be held over the fundus, and removed and re applied from time to time A very powerful remedy is washing out the uterine cavity with a stream of cold water by means of the vaginal pipe of a Higgenson's syringe carried up to the fundus. All these remedies, however, depend for their good results on the fact of the patient being in a condition to respond to stimulus, and their prolonged use, if they *fail* to excite contraction rapidly, will certainly prove injurious. Intra-uterine injection of hot water at a temperature of 100° to 120° has been highly recommended as a powerful means of arresting post-partum hæmorrhage, often proving effectual when all other treatment *has failed* *My own experience* of this treatment is very favourable" He quotes Lombe Atthill as having published cases in which this method was successful and Milne Murray's experiments on rabbits as to the effects of hot and cold water in producing contraction. "Since 1887, plugging the uterine cavity with iodoform gauze and pledgets of cotton has been," he says, "advocated thoroughly in Germany, chiefly by Dührssen but since the publication of his paper a large number of successful cases have been published in which this treatment has been adopted so that it must be admitted as a useful resource in certain intractable cases I have no personal experience of this treatment, but the evidence in its favour is strong It is clearly one which can only be resorted to in very intense cases of hæmorrhage when all other means have *failed* It will obviously be essential to carefully watch the uterus, to make sure that blood is not escaping into and distending its cavity above the plug If the uterine cavity should be only partially or ineffectually filled concealed internal hæmorrhage might very readily be going on without the practi-

without the other." (These two objections, it will be noticed, are mutually destructive, and besides, we are talking to qualified men, not to first-year students—men who, it may be presumed, have been taught to know the actual position of these vessels and their relation to the spinal column beneath—and then he makes what to me is a most astounding statement.) "It is most likely to prove useful in sudden and severe hæmorrhage, and if *it only control the loss for a few moments* it gives us time to apply other methods of treatment. As a *temporary* expedient, therefore, it should be borne in mind. It has the great advantage of supplementing, without superseding, other and *more radical* plans of treatment. If a battery is at hand the Faradaic current may be used, and is, *it is said*, a very powerful agent in inducing uterine contraction. When the hæmorrhage has been excessive and there is profound exhaustion firm bandaging of the extremities, by preference with Esmarch's elastic bandages, *if they can be obtained*, may be advantageously adopted, with the view of retaining the blood as much as possible in the trunk, and thus lessening the tendency to syncope. As a temporary expedient in the worst class of cases *it may occasionally prove of service. Supposing these means fail*, and the uterus obstinately refuse to contract after all our efforts—and, do what we will, cases of this kind will occur—*the only other agent at our command* is the application of a powerful styptic to the bleeding surface to produce thrombosis in the vessels. ...... As it is not proposed by anyone that this means of treatment should be employed until all ordinary methods of evoking contraction have *failed*, and as in cases of this kind the lives of the patients are of necessity imperilled, we should be fully justified in adopting it, even if its possibly injurious effects had been much more certainly proved. ...... Other local astringents may be eventually found to be of use. Tincture of matico possibly might be serviceable. ...... The styptic properties of creoline have already been mentioned. Dupierris has advocated tincture of iodine. Penrose strongly recommends common vinegar and gives directions how to apply it by means of a handkerchief soaked and introduced into the uterus." The italics are mine.

Now, if you refer to the other authors whom I have mentioned you will find that whilst they all agree as to the paramount necessity of evoking contraction they differ as to the value which they place on one or the other of these "remedies." Thus, Galabin[3] says that "there are three serious risks in the injection of perchloride of iron. First, a coagulum may be carried from a uterine sinus and cause pulmonary embolism. Sudden death from this cause has occasionally followed the injection. Secondly, the solution may pass along the Fallopian tubes and set up peritonitis. Thirdly, the clots formed by the iron solution in the uterus, as well as the thrombi in the vessels, are apt to decompose and set up septicæmia." Dakin[4] adds "that the very tough clot formed in the uterus is tenacious and difficult to expel, and it will not improbably putrefy and cause septic trouble." One author strongly advises against the use of ice inside the uterus, inasmuch as ice is often impure and may contain the micro-organisms of tetanus, whilst Playfair himself, as you will have remarked, says that "the use of cold, unless immediately successful, will certainly prove injurious."

I wish you especially to note the frequent repetition of the word "fail"—"if these measures fail, try," &c. Dakin apparently feels so sure that the earlier measures *will* fail that he says "the various manœuvres must succeed one another rapidly, and the preparations necessary for those to follow must be made while any one method is being employed." Am I not justified in saying that the whole tone of their advice is tentative and suggestive of mere experiment? One seems to hear them say, "Try this, that, and the other, but understand that neither I nor anyone else can answer for their efficiency and don't blame *me* if your patient dies."

But ask yourselves, "Of what did this patient die?" Did she die of an uncontracted uterus? Is there such a cause of death at all? No; she died of hæmorrhage. She bled to death just as much as if her carotid and jugular veins had been cut and you had no effective means of stopping the flow of blood from them. Now all writers on this subject subconsciously assume or directly assert that the *only* effective way possible to check hæmorrhage in this situation is by obtaining contraction of the uterus, or failing that by producing firm clots in the open mouths of the vessels concerned. But is that true? Have we no other means? and *how if the uterus cannot contract?* How if we are striving after an end which is unattainable from the first, and from the very essential conditions of the thing becomes more and more impossible with every ounce of blood lost? May not the reason of the whole lamentable business lie here? Writers talk of atony of the uterus, inertia of the uterus, but they talk as if the uterus were a sulky child, able to do what we ask of it if it only would, and only to be coerced by strong measures into doing it; and when we fail, as I will try to show you we are bound *ab initio* to fail, there is a feeling such as a parent has with a naughty child whose obstinacy has withstood a sound whipping and who still sulkily persists in refusing to do what we wish. What else in actual fact have we been doing to the uterus but whip it? Books call it stimulating the uterus to contract. In plain English, it is mere whipping, mechanical, by kneading, flicking with wet towels, forcible compression between one hand inside and one out, between both hands outside, between the hand outside and packing within, or chemical, by ergot and strychnine, any or all of the many ways in which you are counselled to whip this lazy obstinate uterus. It is all, when reduced to simple terms, mere whipping.

We are proceeding upon an implied premiss, which is that the uterus *can* contract if it will; but *can* it? The uterus is a muscle, and, like all muscles, after it has done a certain amount of work there comes a point when it can do no more effectively. Under pressure of will, of external or internal stimulus, it may do a little more, but it will be feeble, ineffectual, spasmodic. Some fibres may not be so exhausted as the rest, and the muscle will then contract irregularly. In the case of the uterus you may then get a temporary hour-glass contraction, a condition by no means to be desired. Every cyclist knows that if when the muscles have reached this stage further work is asked from them cramp follows, and that whilst, if rest is allowed to the tired muscle, it soon recovers its powers, with every additional struggle after it has reached this point, a longer and longer time must elapse before it is again capable of proper use.

Muscles differ not only in different people but in the same person at different times. What we are able to do with our muscles easily and with comfort one year we may find a difficulty in doing another year. And the uterus, being a muscle, shares in this unequal ability. That it has been equal two years ago to do the work of a confinement and have plenty of reserve force afterwards is no proof that there will be any reserve force at all this year, after the contractions necessary to expel child and placenta have taken place. That Mrs. Jones's uterus contracted firmly after a difficult confinement is no reason why we should expect Mrs. Smith's to do so after a comparatively simple and easy time. In every uterus at any given time there is a certain amount of force peculiar to itself alone, and when that is expended you have reached the physiological point of fatigue for that uterus at that time. Before any tired muscle can fulfil its function again properly it must have rest and a reasonable amount of blood circulating in it. But we have been giving this muscle no rest at all, and its blood has been steadily draining away from the first. Can you wonder that we have not succeeded?

Of course, the answer to this according to the present teaching would be, "But we cannot afford to give it rest, because our *only* means of stopping the loss of blood lies in its completing the task required of it, however unfit it may be to accomplish it. No other way is open to us except a measure—that of injection of iron—which may produce sudden death," and the whole gist of the matter lies in the question, "Is this true or not?" One of the most marvellous things to me is that knowledge obtained in one branch of our art is so often absolutely ignored by the teachers of another. Nowhere perhaps is this more flagrantly evident than in this same question of the treatment of post-partum hæmorrhage. Because the blood in this case comes from the interior of a hollow muscle at the end of a normal physiological act, it *ipso facto* apparently ceases to be governed by the laws which are admitted to govern bleeding in all other regions and at all other times, and requires to be dealt with by measures peculiar to itself; measures in which, however, the teachers who recommend them have so little faith that they are never tired of reiterating after each one, "Try this, and if it fails try the next on the list." But is this, of all others, the time for experiments? That these things fail is admitted by the very terms in which their advocates recommend them; that they were bound to fail I think I have shown you. If ever we need a remedy which will not fail we need it here; under such circumstances, if ever experiments are inadmissible it is here and now. But such practice can only be described as at best a series of experiments.

---

[3] Manual of Midwifery, third edition, p. 748.

[4] Handbook of Midwifery, 1897, p. 483.

There is, at the outset, a tendency to confusion in the statement of causation. Every writer almost appears to consider it his duty to pile up a list of possible causes for this bleeding, and these causes are all given pretty much as if they were of equal importance. Most of these so-called causes are not immediate causes at all, but only contributory—such, for instance, as residence in relaxing climates, sedentary habits of life, &c., though they are placed in the same list and as being of apparently the same importance as the rest. Some are extremely rare, as hæmophilia; one, I believe, does not exist—disease of the ganglion cervicale uteri, gravely put forward by one writer. Every man seems to consider it his duty to add one more shovelful to the heap of dust, the clouds arising from which tend to obfuscate the unlucky practitioner's mental vision. And the mention of hæmophilia in this connexion is, though perhaps unavoidable, yet still very objectionable. The very idea of it takes all heart out of the medical attendant, who needs, *au contraire*, to brace himself with the firmest conviction that the hæmorrhage is perfectly under his control and can be infallibly stopped by his efforts. Forget it; wipe it out of your memory altogether. It is the rarest condition possible. Both it and the ganglion idea have served their purpose in filling up death certificates, but they have but little other use. All the other causes are divisible into two plain categories—first, those due to your own conduct of the case; and secondly, those favouring the early appearance of the physiological point of fatigue—producing, in fact, a tired muscle.

Of those causes due to your own conduct it is scarcely necessary to do more than notice them briefly. Though they are not likely to occur in your own practice you may be called in to rectify them in that of others, and therefore I mention them. You will see later that they also can best be dealt with by the plan which I am going to indicate They are: torn cervix, torn vagina, inversion of the uterus, tearing off of the cord, the placenta being partially separated, too rapid and unskilful use of forceps, &c.

There remains, then, but one class, which embraces ninety-nine hundredths of the cases met with—those in which the uterine muscle is tired out at the close of the second stage of labour. The causes included in this class, always given as separate and distinct causes, producing their effects in different ways, but which you can see all agree in producing hæmorrhage only in one way—viz., by hastening the occurrence of fatigue in the muscle—are: the presence of fibroids in the wall, over-distension from hydramnios, development of twins or more children, previous habits of life tending to relaxation of the general muscular fibre, and life in hot climates producing the same result; whilst tedious or prolonged labour simply uses up the normal reserve force usually left after the completion of the second stage, and the point of fatigue so far as the stages are concerned is then reached early. For this class nothing but rest is in the least capable of doing any good How are we to obtain it? and how are we to prevent our patient from bleeding to death whilst such rest is procured? Simply by applying in this situation the accepted rules of surgery in all other situations. Someone once said that surgical writs should run in the sacred cavity of the abdomen as well as in all other regions of the body, and only the remnants of our late superstitious fear of the peritoneum prevent us from a ready assent to this. A similar conservative spirit appears to pervade all that is written on the subject of post-partum hæmorrhage, and the uterus is treated as an organ apart, obeying only its own laws, laws absolutely opposite, apparently, in character, to those which we recognise as true in other regions.

What do we all do, almost instinctively, when confronted with hæmorrhage in any other part of the body? Our minds automatically reflect that all bleeding comes from vessels, vessels of two kinds, arteries and veins, *and can come from no other source*; that of these vessels, arteries come from a parent trunk, the closure of which prevents any loss from smaller branches, however numerous they may be; that veins in the same way converge to one parent trunk; and that if the point at which leakage from them is occurring be elevated above the heart blood will no longer escape from them. If a varicose vein or veins should burst in the leg, is not the first advice given in "first-aid" to elevate the limb? not that it may be as high or a little higher than the patient's head, but well above the level of his heart; and do we not know that the bleeding will at once cease? But such elevation must be decisive and purposeful, not the mere lifting of the bed foot to check syncope, such as described by Playfair. The uterus itself must be raised until it is higher than the heart, and that means of course that the foot of the bed must be lifted much higher. The best thing, I believe, because the quickest, is to run a table underneath and to allow the foot of the bedstead to rest upon this; by such means you at once place the patient at an angle of 45° or 50° with the ground, but a chair with footstools or books piled upon its seat will do. The great thing is to take the readiest and quickest means of practically placing the patient in the Trendelenburg position. Elevation of the legs has another advantage, that it favours the return of blood from the lower extremities and so takes the place of another and favourite manœuvre of those who have separate plans for all these indications and do not grasp and attack from the point of view of the main principles involved—that of bandaging the legs upwards. Such bandaging takes time and after all only effects the one thing, the emptying of the vessels of the lower extremities.

Having controlled the venous loss we have the arterial to consider. The fact that blood is coming from 50 or 100 open tubes is of no importance if these tubes are all fed from one trunk If we can control the trunk we close them all. But do they all come from one source? In a way they do, because they are all supplied from the aorta; practically they do not, because about one-sixth comes through the ovarian arteries, which arise from the aorta at a relatively high point above that at which we can apply pressure. Fredet, indeed, says that in the normal unimpregnated uterus the ovarian arteries do not supply the uterus at all, all the blood going to this organ coming from the uterines, that there is a complete break up of the ovarians into capillaries before they anastomose with the capillaries belonging to the uterines. I believe that, even if this is true, it is not always the case, and moreover that during the general development of the blood-supply attendant upon pregnancy the connexion between the two systems becomes much fuller and more direct, but even then you will see how much less relatively of blood is obtained from the former source. Five-sixths at least come through the uterine arteries which, coming from branches at the very end of the aorta, are controllable by pressure at any point along its trunk The objection raised to pressure upon the lower part of the aorta, the plan which I recommend, is that thereby you do not absolutely shut off all blood supply, but only five-sixths or so. But further consideration will show that this is no objection at all, that, on the contrary, it is a very great advantage. What is it that we wish to do? We wish to prevent the patient from bleeding to death whilst the uterine fibres obtain their absolutely needed rest During that rest, if it is to be of any value, if it is to yield us the desired result of fresh effective contraction, those fibres must have a certain amount of healthy blood circulating amongst them If we could absolutely prevent any blood from reaching them they could not recover. At the end of the time, however long it might be, the uterine fibres, the natural ligatures of the open vessels, would be as powerless to contract and to tie these vessels as when we began. Probably, indeed, they would be in a far worse condition, because they would be practically dying or dead. What we want is rest and recuperation, not necrosis. It would seem, indeed, as though the construction of the arterial supply to the uterus had been specially designed for our assistance in cases of this kind—that Nature herself has pointed out the way for treatment. "Block," she seems to say, "the main current of blood through the more direct route, that of the uterine vessels. Your patient cannot then lose any dangerous amount of blood. Meanwhile I, through the longer and more devious channel of the ovarians, will keep up a sufficient supply of blood, coming with no great force and in no great quantity, to preserve the vitality of the organ, assisting in the formation of small plugs in the open arterial mouths, vivifying and strengthening the muscular tone, which temporarily is at too low an ebb, so that when once more the full force of the blood-current is allowed to bear upon them the vessels shall be found closed by clot and constricted by the now firmly contracting fibres around "

How is all this to be brought about? Very simply indeed. The closed fist is applied with its ulnar surface resting upon the aorta as it lies over the left side of the vertebral column, and just sufficient pressure is exerted obliquely backwards and towards the right so as to enable it to compress that vessel against the unyielding surface beneath. At any point accessible over the course of the abdominal aorta this compression can be exerted and there is always a sufficient extent to enable us to vary the site of impact. The prolonged tension of the abdominal walls which was inevitable during the preceding pregnancy has rendered them so lax and unresisting now that the uterus is empty, that the vessel is readily found and as readily controlled. At first, if the patient has lost much, the sensation of pulsation against your hand is very faint, but it is astonishing how quickly this becomes more and more distinct until within a very short time the blood, now virtually imprisoned in the upper half—the only important part—of the body, raps vigorously at the closed door. Whilst this compression is kept up it is an easy matter to clear the uterus of clots, portions of placenta, membranes, &c., so that when the uterus begins again to contract its newly-regained strength may find no needless work to do in ejecting them. Any tear in the genital canal can be explored and reunited, and all with perfect ease to the practitioner and safety to the patient since the area of operation is no longer obscured by floods of blood.

If you look back you will remember that we noticed that firm traction upon the uterus checked the bleeding, and that whilst this traction was kept up we were able to plug the uterus, but that as soon as the os was allowed to re-ascend, or at all events within a few minutes, it became obvious that once more bleeding had recurred. Why did this happen? and what light does it throw upon the proposed method of treatment? As we all know, the uterine arteries make an acute angle in their course when they reach the uterus on either side. This angle in the normal condition is so curved as not to obstruct at all the flow of blood in the vessel at this point. A little increase in the acuteness of the angle, however, such as is produced by firm traction on the uterus, effectually kinks and closes these vessels, and you have practically the same effect, so far as the blood-supply is concerned, as you obtain by pressure on the aorta below the origin of the ovarian arteries—a shut-off of the supply of blood through the uterine arteries. This proves two things: first, that the main supply, the only dangerous supply, the supply which permits of such a loss as may be called flooding, comes through the uterine arteries; and, secondly, that if these are closed by any means the flooding ceases. You may say, Why not, then, keep up this traction alone? Well, in the first place, prolonged traction upon the os means wounding the os, possibly tearing out, and in any case the presence of a foreign body in the vagina and therefore increased risk of sepsis. Why should we run these risks when we have as certain, as scientific, and infinitely more easy a method in external aortic compression? Landau's method of vaginal hysterectomy, which consists in splitting and removal of the uterus without previous ligation of its vessels, is based upon this fact. From the first incision to the last firm traction is maintained upon the uterus, and this organ can then be divided from top to bottom without the loss of a teaspoonful of blood.

I scarcely care to say anything about compression of the aorta by the hand inside the uterus. To some minds it would appear as though a simple and easy method must be objected to because it *is* simple and easy and appeals to common sense—that for it something else more difficult, more dirty, and infinitely more dangerous must be substituted, although the result aimed at and obtained is precisely the same. It may be that the dirty method has the advantage of having been recommended by some foreign authority, and that to them is all sufficient. I do not waste your time in discussing it further. As to the length of time during which this compression should be kept up, a surgeon compressing the main artery of a limb keeps up his pressure until all the vessels arising from that main artery which had been bleeding are tied. In this case our ligatures are the revived fibres of the uterine wall, and we must wait until these fibres begin again to contract. It will be found in practice that this pretty much coincides with the firm, strong impact of the blood-current against the compressing hand; when the force of this has well revived, so also will the muscular force of the uterus be found rejuvenated; but the other hand of the surgeon can easily judge from time to time of its occurrence, no longer pounding and kneading its fibres in a hopeless struggle to *make* it contract, but gently touching it from time to time in order to gauge its condition and its tendency to contract of its *own free will*. It is then that the compressing hand is very slowly and gradually lifted, not permitting the full force of the aortic current to drive against the clots already formed by the blood from the ovarian arteries all at once, but gradually more and more, as they prove their capacity for secure hæmostasis. When once this is the case the hand may be removed, and the contraction now established, being a natural one, will be found to be also, and, therefore, a trustworthy one. For four or five minutes the parts should be watched. It is, of course, possible that one may have removed the controlling pressure a little too soon. The force of the aortic current may have driven out some of the newly formed plugs and some hæmorrhage may recur. If, however, you have fully understood the plan upon which you are proceeding you will feel able to consider this of but little importance. You will simply replace your pressure for a short time longer, knowing that you have now to deal with a reviving, not an exhausted, uterus; that some of the plugs still remain and are moment by moment becoming firmer, harder, better gripped by the recuperating fibres around; that the open mouths of the vessels from which these plugs have been dislodged are being moment by moment decreased in calibre; that the fresh clots which are again forming there do not require therefore to be so large as before. In a while you remove your hand again with increased caution and greater slowness and deliberation to find that now all is secure. There is all the difference in the world between being consciously on the up-grade and being steadily on the down-grade. You will leave the bed in its inverted position for 24 or 48 hours; not now so much to check venous bleeding as to favour the concentration of the amount of blood remaining in the patient, which must necessarily for a while be less than normal in and around the vital centres.

Now, this and this alone is, I conceive, the one and only primary duty of the medical attendant in these cases. All other things are subsidiary and must never interfere with or lessen in effectiveness this proceeding. If one hand is tired the other can be substituted, the second being well in place and effective before the pressure on the other is lessened and removed. If both hands are tired it is easy to teach the nurse to replace your own by hers; incidentally it may be pointed out that it would be practically impossible to teach her to replace yours if it were inside the uterus, whilst even if it were such pressure could not be continuous, which is essential to success. During the time that the nurse or your medical friend keeps up the control you can, if you choose, transfuse with or inject per rectum saline solution—a perfectly useless measure so long as leakage is persistently going on; you can clear out clots, pieces of placenta, membrane, &c.; you can mend tears, sew up a split perineum, do anything advisable in perfect safety and with perfect ease, since the area in which you are working is clear of blood, and the patient is quiescent, her cerebral centres being well supplied.

I fear that you may consider all this as somewhat didactically expressed. At the same time, you will see that the main reason for my bringing forward this subject is that teachers of obstetrics have always spoken tentatively and hesitatingly with reference to it; that they hold no doctrine strongly; and that therefore, in direct consequence of this hesitancy, their disciples find themselves, when called upon to act, in a pitiable state of uncertainty. If I had had nothing clearer and more definite to offer you I should but have wasted your time and my own. Holding these opinions as I do with absolute certainty, because based upon anatomical and physiological facts supported by repeated experience of the results of the treatment which I have sketched out, I should but leave your minds in the same condition of doubt which should here be impossible had I not spoken as forcibly and clearly as I was able.

Manchester.

THE SANITARY INSPECTORS' EXAMINATION BOARD.—The next examination for certificates of qualification for appointment of sanitary inspector or inspector of nuisances, under Section 108 (2) (*d*) of the Public Health (London) Act, 1891, will be held in London on Tuesday, May 7th, and the four following days. Particulars will be forwarded on application to the honorary secretary, Mr. W. R. E. Coles, 1, Adelaide-buildings, London Bridge, London, E.C.

REMARKS ON ENLARGEMENT OF THE INGUINAL GLANDS CHIEFLY IN CONNEXION WITH THE DIAGNOSIS OF PRIMARY SYPHILIS.

BY ARTHUR COOPER, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE WESTMINSTER GENERAL DISPENSARY.

IT is well known that evidence based on the condition of the inguinal glands frequently forms an important factor in the diagnosis of affections of the genito-urinary organs, but the correct interpretation of evidence thus obtained is by no means always an easy matter. The main purpose of what follows is to draw attention to the fact that in many cases, and notably in the case of primary syphilis, the diagnostic value of inguinal glandular enlargement depends more on the circumstances of the particular case than on what may chance to be discovered in the groins at any particular time.

Now, in the examination of any case in which there is a lesion within the area drained by lymphatics which go to the inguinal glands, the first thing is to be careful not to assume without due inquiry that any glandular enlargement which may be present at the same time is the direct consequence of that lesion. Another important point to bear in mind is that different persons vary greatly as regards susceptibility to glandular enlargement. Tuberculous subjects seem to be most liable to have the lymphatic glands affected on slight provocation, but many others, apparently not tuberculous either in person or history, also have easily vulnerable glands. This difference in susceptibility is well shown by those cases, so common among the lower classes, in which one child with an unhealthy throat or a dirty head, and sometimes without any discoverable local cause, will have more or less enlargement of the cervical or occipital glands, whilst another child in apparently similar circumstances may have no perceptible enlargement of the glands at all. The same observation also applies, though this is not so generally recognised, to the inguinal glands, and it is a fact that many men and boys[1] who make no complaint whatever have enlargement of these glands to an extent which, although in itself of little moment, may yet in certain circumstances become of considerable importance, as will be seen by-and-by. In some of these cases, no doubt, there has been acute adenitis in connexion with some previous morbid process, but in many others—which are more likely to cause difficulty in diagnosis later—the patient is unaware of the presence of enlarged glands, or if he knows it is either unable to throw any light on the subject or mentions some such cause as a strain in jumping, or running, or riding on horse or cycle. In some cases, perhaps, no other cause can be detected by the surgeon either, but in most of them, I think, either with or without a history of strain, some form of mild but long-continued irritation is present, and this is most frequently balano-posthitis, not necessarily enough to cause discomfort, but merely such a condition as may be due to a prepuce not always very long or very tight, but worn habitually forward and insufficiently cleansed. Chronic glandular enlargement of this kind is usually slight both in degree and in the number of glands affected—sometimes only one in one groin, sometimes one in each groin, some- [illegible] in the other, rarely more than [illegible] the glands are, as a rule, [illegible] But whatever may be the cause the important point is that a man who is apparently healthy and without any history of venereal or other disease to account for it may, knowingly or not, have a degree of indolent enlargement of the inguinal glands which of itself is indistinguishable clinically from that which is found in some cases of primary syphilis. And here it may be remarked that too much is sometimes expected in the way of glandular enlargement as well as of induration of the primary lesion in syphilis. In many cases, no doubt, both are so well marked that the diagnosis is easy enough. But in syphilis, as in other diseases, a large number of cases are not typical according to the text-book description, and thus are more or less liable to be overlooked or mistaken, and yet if due attention be paid to details which are sometimes considered too trivial for notice most of them ought to be diagnosed with as much certainty as the so-called typical examples.

Before going further it will be convenient to describe *briefly the characteristics of the adenopathy of primary* syphilis. When no complication is present and when the groins were clear previously the glands first become palpable at some period during the fortnight following the appearance of the primary lesion. The exact time varies in different cases, but it seems to be most commonly about 10 days. The enlargement is gradual and progressive—that is to say, one gland enlarges first and is soon followed by others, but the first usually attains a larger size than those which follow. The enlargement goes on slowly until a group of glands, the number of which varies in different cases, can be plainly *felt* and sometimes *seen in both groins.* The glands then seem to remain stationary for a time and they afterwards slowly diminish and finally disappear in the same gradual manner. In typical cases, and when the enlargement has reached its height, a group of glands from three to six or even more in number can be felt in each groin. But besides being multiple the glands are also indolent and separate—that is, they are not tender when handled and each can be clearly defined and separated from the others by palpation. They are also freely moveable beneath the skin, are of moderate size, and are more or less hard. Hardness, however, is a variable quality in syphilitic as in other affections of the glands, and the same remark applies also to the shape of the glands, though one sometimes hears of "*amygdaloid*" *or* "*bullety*" *glands, as if such* terms had special significance. Both groins are usually affected, though the number of glands in each often varies considerably; but sometimes all the glands are in one groin and that not always on the same side as the primary lesion.

When all the features mentioned above are present and when those of the primary lesion correspond the diagnosis is easy. But the cases with which we are now chiefly concerned are those which are atypical and in which the diagnosis is sometimes difficult. The glands, for example, may be few in number and insignificant in size, the state of the groins, in fact, being merely such as has already been described to be not uncommon without syphilis. If, then, a patient comes for advice with enlarged glands accompanied by some form of lesion of the genital region the first question we have to decide is whether the enlarged glands are due to that lesion or not. And if we know nothing about the previous condition of the groins this point cannot be decided at once by the glands themselves, though taken in conjunction with the primary lesion and the *history we may be able* to arrive at a correct diagnosis. When we are unable to do this at the first visit the exact state, both of the primary lesion and of the groins, must be noted down for future reference, and if the examination be repeated at sufficiently frequent intervals and the peculiarities and course of syphilitic adenopathy be borne in mind we shall rarely fail to determine the nature of the case in a short time. But if in such a case we happen to know what the condition of the groins was beforehand we shall obviously be in a much better position for making an immediate diagnosis. It is an excellent rule, *therefore, to make a practice of taking note* of the groins as a matter of routine in patients whom we may have to examine for any reason, and all the better if this knowledge be acquired before there has been any risk of contagion, for such a knowledge of what may be called inguinal "geography" may make all the difference between a prompt and a tardy diagnosis should any venereal or other disease show itself later. To illustrate this let us suppose that a man whom we know to have had clear groins previously exposes himself to the risk of contagion and after an interval comes to us with some form of primary lesion which has not [illegible] gland a little large[illegible] or on the opposite side, even by that time the evidence of syphilis will be considerable, provided, of course, that the character of the primary lesion, and perhaps the history also, are not altogether opposed to this view. On the other hand, a similar degree of glandular enlargement of unknown origin [illegible] is doubtful [illegible] for the time being, [illegible] been [illegible] far [illegible] as the glands are concerned [illegible] have to wait and to watch, but in the last we start with the advantage of knowing that two glands, at any rate, are not syphilitic.

---

[1] I am not sure how far these remarks would apply to women.

The exact duration of primary syphilitic adenopathy is a difficult question, for it must be remembered that, after the secondary stage has been reached the inguinal may share with other glands in a more generalised adenopathy which is independent of the position of the primary lesion and therefore beyond the scope of the present remarks. It will be sufficient to say here that the duration of the primary adenopathy probably varies within certain limits according to the particular case, partly owing to the effects of treatment and partly to the presence or absence of complications, but that the whole course is usually comprised within a period of a few months. For our present purpose the gradual and progressive character of the change is the most important point, and it must also be remembered that the enlargement is only a temporary one, wherein it differs from the simple form before mentioned which may remain apparently unaltered for many months or even years and sometimes perhaps permanently.

Among the various causes of atypical adenopathy it is perhaps hardly necessary to mention the previous removal of some of the glands by operation or their destruction by some morbid process. In such patients if syphilis be afterwards contracted the extent of glandular change will depend on what has happened beforehand in each case, but the presence of scars in the groins will usually be sufficient to prevent mistakes in diagnosis.

Besides the numerous cases in which the primary adenopathy is slight or otherwise atypical there are rare instances in which no glands can be felt. In most of the cases of this kind that I have seen the patient has been either very fat or in the habit of wearing a truss, the pressure of which seems occasionally to prevent enlargement of the glands. Cases have also been recorded of absence of enlarged glands in connexion with a phagedenic primary sore.

Although primary syphilis of itself probably never causes acute inflammation and still less suppuration of glands, yet as complications both occur not infrequently, especially among the lower classes.[2] For we may have a mixed infection of the glands just as we have in the case of the sore, and if the sore inflames and suppurates the glands may follow suit, and thus the distinguishing characteristics of both may be temporarily obscured. Periadenitis may be slight and sub-acute and merely sufficient to mask the outline of the syphilitic glands, or it may go on until they are all glued together into a large irregular mass known as a "conglomerate bubo" which may or may not suppurate according to circumstances. When the glands are affected early, as in the case of the local chancre, for example, a sharp look-out must be kept on both sore and glands, so that the changes peculiar to syphilis may not be overlooked when the incubation period has elapsed.

But in addition to these accidental complications there are others which are avoidable and which, therefore, ought not to occur. I refer to those due to the application of irritants[3]—especially nitrate of silver—to venereal sores and iodine preparations to the groins. This has been a fruitful source of diagnostic error in the past and to a certain extent probably is so still.

Although multiple indolent glands form one of the most important features of primary syphilis, it must be remembered that they are not in themselves proof of it, and that an apparently typical condition of the groins is sometimes due to other causes, more especially in persons whose glands are unusually susceptible. Among such cases may be mentioned severe gonorrhœa, urethral irritation from too strong injections or other injury, irregular herpes, severe balano-posthitis, and tuberculosis. The diagnosis will depend on the history, on the absence of an indurated primary lesion, and on careful watching throughout the incubation period of syphilis.

It may not be out of place, perhaps, to say a word about examining the groins, for if the examination be made carelessly but little real information will be gained. Digging the fingers into the groins of a sensitive patient in the upright position is quite unlikely to lead to any useful result. In all doubtful cases, therefore, and, indeed, whenever accuracy is desired, the patient should be lying down. In many cases when he is standing up muscular contraction prevents a complete examination and, moreover, what may appear to be an indefinite thickening in the groin in the standing position can often be resolved into several glands in the supine position. With the patient lying down, then, with the muscles relaxed and with the inguinal regions fully uncovered, each groin should be gently and deliberately gone over with the fingers of one hand, and as each gland is found a finger tip of the other hand is placed on it and kept there until the whole groin has been examined. The number, position, form, and size of the glands are then noted down at once for future reference, and for this purpose I have found a rough and simple diagram like this  of great assistance. A series of figures of this kind will often convey more information about the state of the groins than many lines of writing.

It must be familiar to everyone that whenever the subject of visceral or other late form of syphilis is discussed by physicians there is general agreement respecting the frequent absence of any clear history or other evidence of the earlier signs of the disease. Indeed, it seems to have been chiefly this circumstance that led an eminent physician to suggest not long ago that what is generally known as the local or soft chancre may be responsible for some of the nervous maladies now attributed to syphilis. But whether this suggestion be or be not substantiated by future observation it would not do any harm in the meantime to those of us who are more accustomed to see and to treat primary syphilis if we were to look upon this frequent absence of early history as a hint that perhaps we are not always sufficiently careful in our diagnosis. There can be no doubt that for some reason or other a considerable number of cases of syphilis are overlooked or mistaken—and consequently untreated—in the earlier stages. In the great majority, of course, the fault is that of the patient himself who is either too unobservant to notice the early signs or too careless to seek medical advice if he does notice them, and in many others, though he may take advice at first, he neglects to follow it and to present himself for examination during a sufficient length of time. But there still remain a certain number of cases to be otherwise accounted for, and I venture to think that these might be diminished by careful attention to matters of detail which, as I have before remarked, are sometimes considered too trivial for notice.

The diagnosis of primary syphilis, it should never be forgotten, is based not on any one sign but on three things: (1) the history; (2) the primary lesion; and (3) the state of the nearest gland or glands. The first of these, for which we have to trust the patient, is often unfortunately too vague to be of much use in diagnosis, though it is of real value in some cases and therefore should not be neglected. The other two can be observed by the surgeon himself and should always be closely watched for a sufficient length of time, having regard to the incubation period. If this were always done and if—which is quite as important—nothing were done by the patient or the practitioner to interfere with the diagnosis probably few cases of syphilis would escape detection during the primary stage.

In what has been written above I have tried to indicate some of the points in connexion with the last-mentioned though not least important of the three factors on which the diagnosis of primary syphilis depends.

Old Burlington-street, W.

THE MEDICAL GUILD.—The annual report and balance-sheet of the Medical Guild for 1900 states that the council of the Guild has held 14 meetings during the past year and many meetings of sub-committees have been held. The subjects dealt with included Reform of Provident Dispensaries, Club Practice, Hospital Reform, and Legislation for Midwives. A conference was held between the Guild and the Provident Dispensaries Medical Officers' Association, which it is hoped will be productive of good results. With regard to club practice the question of representatives of the Guild attending a meeting of the council of friendly societies in Manchester is being considered. A conference of medical societies organised by the Guild is to be held in Birmingham this year on the lines of that held last year in Manchester. The total number of members at the date of the report is given as 219 and the finances show a balance of close upon £50.

---

[2] Of 116 cases of primary syphilis treated by the late Mr. Berkeley Hill and myself at the Male Lock Hospital 10 had acute suppuration of the inguinal glands.

REMARKS ON THE HOLMGREN TEST.

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.

THERE are few points in medical practice in which the change of opinion has been more complete than that with regard to the Holmgren test for colour-blindness. If there be at the present time any specialist who is in doubt about its efficiency I shall be only too pleased to give him an opportunity of examining a case which has passed the test even under the most rigid and careful examination. The reader will probably think that this being the case it is hardly necessary to again draw attention to its defects and the necessity of having a proper test. A few years ago the Royal Society appointed a committee to decide upon an efficient test for colour-blindness and the Board of Trade are now using the Holmgren test at the recommendation of that committee and thereby endangering the lives of thousands of persons. Few will credit, unless they have tried, how exceedingly difficult it is to convince men of a perfectly obvious and easily ascertained fact if this fact be in opposition to their preconceived notions. In all ages it has been so and probably always will be so, but there is no doubt that a very great advance will be made in knowledge when scientific men recognise this psychological source of error and cease to reject facts without considering them because they are so certain that the facts are wrong that they will not even take the trouble to confirm their convictions. It will be of untold advantage to knowledge when this obstacle is removed from the path of the earnest seeker after truth

It is not my object in this article to point out in what way this test is defective—this I have already done many times in the minutest detail[1]—but to give the opinions of others, including those who had previously opposed me most strongly I must, however, mention that the test is very inefficient; a great number of normally sighted persons are rejected and three divisions of the dangerously colour-blind nearly always escape detection by it. It may be a matter of surprise to those who know the facts of colour-blindness as they are to be found in the text-books that the test can possibly fail. The reason is that the majority of the so-called facts are erroneous The writers have put down the facts as they ought to be according to some theory of colour-vision, not as they really are.

The President of the Ophthalmological Society, Mr. Anderson Critchett, writes. "I do not regard the Holmgren test as a perfect one."

Mr. T. H. Bickerton writes as follows[2]: "To be perfectly candid, I was, up to a comparatively recent date, a firm believer in the all-sufficiency of the test. In fact, I informed the Royal Society Commission which investigated the seamen's eye-sight question that I was prepared to pin my faith to the Holmgren wool test. Some little of this confidence has, I need hardly say, been shaken by the discovery of the phenomena to which I have alluded." Mr. Bickerton also quotes Dr. Hubert Seager, Dr. G. Mackay, and Dr. Angus McGillivray.

Dr. Seager writes: "I do not remember to have yet seen any discussion on the peculiar form of colour-blindness to which I myself, and no doubt other people as well, are subject—inability to distinguish at night between a red and a green light at a distance exceeding half a mile, though I can pass any test for colour or long sight in the daytime and can distinguish coloured lamps perfectly at night within half a mile's distance. I tested this condition of my eyesight again last year when I was at sea for a week or two and found it unaltered Naturally such a state of colour-blindness might lead to very serious accidents at night and the Board of Trade tests should be adapted to such defects"

Dr. Mackay writes on the subject as follows: "It seems to be scarcely appreciated as it ought that there exist persons whose perception of colour appears to be correct in quality but is congenitally defective in quantity or intensity. The subjects of this affection can pass successfully such a test as Holmgren's applied in the orthodox way since they inspect the skeins at close quarters. They appear to see colours much or quite as the normal eye provided the stimulus of colour rays applied to their retina is sufficiently strong, but if it be weakened by dilution with white light or removal of the source of colour to a distance their defect is made manifest."

Dr. McGillivray remarks as follows: "Now a candidate may arrange the Holmgren tests with perfect accuracy and recognise and name promptly the colours used in signalling, yet, though possessing perfect distant vision, he may be quite unable to tell the difference between a red and a green signal at the distance of a few yards even in a clear atmosphere."

Dr. Karl Grossmann writes: "Not so long ago a case came under my notice where a red-green blind person, very well educated, acquitted himself perfectly well of the examinations (repeated ones) with Holmgren's wools but failed to recognise some of my glass letters and other tests. I am sorry to have to keep the gentleman's name to myself, as he strongly objects to having his defect known, but for those who perhaps think my experience in this instance too exceptional I need only refer to similar experiences published by Professor Pfluger of Berne. He found in a post-graduate course of ophthalmology which he was then giving to 16 army surgeons that there were two of them completely red green blind, as proved by his own and other tests, but when tried with Holmgren's wools they made not the slightest mistake. This may suffice to show that Holmgren's test is not sufficient for every case of colour blindness. Especially in the case of the educated we have to be extremely careful, and men who prepare for the command of a ship belong to this class."

Dr. Lindsay Johnson writes · "I consider your lantern test and neutral glasses as absolutely necessary to supplement the wools."

Mr. Judge Baldwin, Mr A St. Clair Buxton, and Professor H. Cohn have also pointed out the defects of Holmgren's test, and the two latter have given cases of colour-blindness which have escaped detection by the test.

Mr. E Nettleship examined one of my trichromic cases and very kindly allowed me to state when I showed the case subsequently at the Ophthalmological Society of the United Kingdom that the man had been examined and passed by him.

I have many more letters in confirmation of the above.

Incredible as it may seem, the report of the Committee of the Royal Society contains internal evidence that the Holmgren test is not satisfactory. The last page of the report gives a summary of the cases of colour-blindness detected at the examination of about 300 railway employés. There are two facts to be noticed—first, that five colour blind persons escaped detection by the wool test; and, secondly, that no colour-blind person escaped detection by all the lantern tests—that is to say, that though a colour-blind person was passed by one lantern test the same man was rejected by another examiner using another lantern test. The obvious conclusion is, therefore, that a lantern test could be constructed that would detect all cases.

I think that it will be admitted that I have made out a case for a fresh inquiry into the subject. What we want is a careful and unbiased inquiry. All facts should be carefully examined and should not be rejected without consideration because they do not fit in with a particular theory.

THE CHEMISTRY OF NERVE-DEGENERATION.[1]

BY F. W. MOTT, M.D., F.R.C.P. LOND., F.R.S.,
AND
W. D. HALLIBURTON, M.D., F.R.C.P. LOND, F.R.S.

WE have previously shown that in the disease general paralysis of the insane the marked degeneration that occurs in the brain is accompanied by the passing of the products of degeneration into the cerebro spinal fluid. Of these, nucleo-proteid and choline are those which can be most readily detected. Choline can also be found in the blood. We have continued our work and we find that this is not peculiar to the disease just mentioned, but that in various other degenerative nervous diseases (combined sclerosis, disseminated sclerosis, alcoholic neuritis, and beri-beri), choline can also be detected in the blood. The tests we have employed to detect choline are mainly two: (1) a chemical test—namely, the obtaining of the characteristic octahedral crystals of the platinum double salt from the alcoholic extract of the blood; and (2) a physiological test—namely, the lowering of blood-pressure (partly cardiac in origin and partly due to dilatation of peripheral vessels) which a saline solution of the residue of the alcoholic extract produces; this fall is abolished or even replaced by a rise of arterial pressure if the animal has been atropinised. It is possible that such tests may be of diagnostic value in the distinction between organic and so-called functional diseases of the nervous system. The chemical test can frequently be obtained with 10 cubic centimetres of blood.

---

[1] Abstract of a paper read before the Royal Society on March 14th, 1901

A similar condition was produced artificially in cats by a division of both sciatic nerves, and is most marked in those animals in which the degenerative process is at its height, as tested histologically by the Marchi reaction. A chemical analysis of the nerves themselves was also made. A series of 18 cats was taken, both sciatic nerves were divided, and the animals were subsequently killed at intervals varying from one to 106 days. The nerves remain practically normal as long as they remain irritable—that is, up to three days after the operation. They then show a progressive increase in the percentage of water and a progressive decrease in the percentage of phosphorus until degeneration is complete. When regeneration occurs the nerves return approximately to their previous chemical condition. The chemical explanation of the Marchi reaction appears to be the replacement of phosphorised by non-phosphorised fat. When the Marchi reaction disappears in the later stages of degeneration the non-phosphorised fat has been absorbed. This absorption occurs earlier in the peripheral nerves than in the central nervous system. This confirms previous observations by one of us (M.) in the spinal cord in which unilateral degeneration of the pyramidal tract by brain lesions produced an increase of water and a diminution of phosphorus in the degenerated side of the cord, which stained by the Marchi reaction.

The paper is illustrated by tracings of the effects on arterial pressure of the choline separated out from the blood of the cases of nervous disease mentioned and from the blood of the cats operated on. Tables are also given of the analyses of the nerves and drawings and photo-micrographs from histological specimens of the nerves. A summary giving the main results of the experiments on animals is shown in the following table:—

Days after section.	Cats' sciatic nerves.			Condition of blood.	Condition of nerves.
	Water.	Solids.	Percentage of phosphorus in solids.		
Normal	65·1	34·9	1·1	Minimal traces of choline present.	Nerves irritable and histologically healthy.
1–3 ...	64·5	35·5	0·9		
4–6 ...	69·3	30·7	0·9	Choline more abundant.	Irritability lost; degeneration beginning.
8 ...	68·2	31·8	0·5	Choline abundant.	Degeneration well shown by Marchi reaction.
10 ...	70·7	29·3	0·3		
13 ...	71·3	28·7	0·2		
26–27 ..	72·1	27·9	Traces.	Choline much less.	Marchi reaction still seen, but absorption of degenerated fat has set in.
29 ...	72·5	27·5	0·0		
44 ...	72·6	27·4	0·0	Choline almost disappeared.	Absorption of fat practically complete
100–106	66·2	33·8	0·9		Return of function; nerves regenerated

IN consequence of the death of Professor Manassein of St. Petersburg we regret to learn that the *Vrach*, the foremost medical weekly paper in Russia, which was founded by him, is likely to be discontinued, at all events after the close of the current year.

A CASE OF ERYTHEMA SCARLATINIFORME DESQUAMATIVUM.

BY C. KILLICK MILLARD, M.D., D.SC. EDIN.,

MEDICAL OFFICER OF HEALTH, BURTON-ON-TRENT.

As comparatively few cases of this disease have been recorded in this country, and as from a diagnostic point of view the affection is of importance on account of its resemblance to scarlet fever, the following case may be of interest. The case was under the care of Mr. E. C. Stack, F.R.C.S. Irel., by whose courtesy it was brought to my notice.

The patient, a man, aged 36 years, was attacked on Nov. 24th, 1900, with slight pyrexia and malaise accompanied by an intense universal scarlatiniform eruption. He was first seen by me on the 26th. The eruption was then beginning to fade. It consisted in a diffuse erythema affecting the skin everywhere, including the face, the palms of the hands, and the soles of the feet, and presenting an appearance closely resembling that of a severe case of scarlet fever. The tongue was slightly furred, but the fauces appeared to be unaffected. The pyrexia and malaise had now passed off. On the 27th, three days from the onset, desquamation set in, beginning on the upper part of the chest, and it rapidly involved the whole surface, the palms of the hands and the soles of the feet being affected last. The process developed just as in scarlet fever, but with more rapidity. It was very profuse, the epidermis in some parts coming away in sheets. It continued for about three weeks, the patient returning to work at the end of that time after making an uninterrupted recovery. An examination of the urine revealed nothing abnormal. The patient, who otherwise had enjoyed good health, had suffered from attacks similar to the above ever since he was a child. They usually recurred about once every 12 months, irrespectively of season. He once, however, had two attacks in three months. He had never been able to account for them in any way and was unaware of any cause, dietary or otherwise, tending to determine them. They came on quite without warning, the first noticeable symptom being a feeling of burning heat in the skin immediately followed by the appearance of the eruption. The latter usually appeared first about the genitals and rapidly invaded the whole surface of the body. It was not specially irritating. There were usually some headache and malaise at the onset, but they were not severe and soon passed off and the appetite was not affected. The constitutional disturbances, indeed, appeared to be very slight. Desquamation always began within two or three days, appearing first about the neck, the shoulders, or the face, and last upon the hands and feet. It was always profuse and on one occasion, several years ago, the nails were shed. The process was usually completed in about three weeks. During an attack he would remain at home, but never in bed. The attacks had more than once been diagnosed as scarlet fever until the full history was given and his appearance at out-patient departments was apt to cause a commotion. The patient had eight brothers and sisters, all healthy, but two cousins, he believed, suffered in a somewhat similar way but to a less extent.

The above appears to be a typical case of idiopathic erythema scarlatiniforme desquamativum. The disease is a rare one in this country, but is more common in France, and our knowledge of it is chiefly due to the French dermatologists Bercier and Brocq. Erythema scarlatiniforme desquamativum is a febrile non-infectious exanthematous affection. The tongue may be furred, but it is never a typical "strawberry" tongue, and the fauces are unaffected. Pyrexia is usually slight, but the temperature may occasionally reach 103° or 104° F. The eruption is generally universal and intense, and it closely resembles that of scarlet fever. Desquamation always sets in early, a point of some diagnostic importance, and is usually profuse, the hair and nails being sometimes shed [illegible] ed to regard the [illegible] The etiology is [illegible] and to depend upon predispos [illegible] to recur. Amongst the causes [illegible] septicæmia and pyæmia; (2) [illegible] and typhoid fever; (3) rheumatism, ague, chronic Bright's disease, (4) sewer gas poisoning (Crocker); and (5) drug manifestations The disease is to be distinguished from scarlet fever by the absence of throat symptoms, by the disproportion between the intensity of the eruption and the amount of pyrexia, by the absence of the "circum-oral ring," and by the early onset of desquamation. When there is a history of recurrent attacks, as in the present case, the diagnosis should be easy. The prognosis in idiopathic cases is favourable In other cases it will depend upon the associated cause The treatment must be on general principles, but is unsatisfactory Arsenic is to be avoided.

Burton-on Trent

NEUTRAL RED AS A MEANS OF DETECTING THE PRESENCE OF THE BACILLUS COLI COMMUNIS IN WATER SUPPLIES.

By William Hunter, M.B, C.M Aberd,

Assistant Bacteriologist to the London Hospital.

(From the Bacteriological Laboratory, London Hospital)

Quite recently I showed[1] that the use of neutral red as suggested by Rothberger afforded a reliable method of distinguishing the bacillus coli communis from the bacillus typhosus, and further, that it was possible to diagnose by means of this method with certainty the presence of the bacillus coli communis in the majority of fluids within from 12 to 24 hours At my suggestion Dr. Makgill has made some experiments with the object of finding whether this reaction affords a means of detecting the bacillus coli communis in water supplies and of estimating thereby the number of bacilli present. The following is a summary of the results obtained

Media containing neutral red form an extremely delicate test for the presence of the bacillus coli communis. This is most marked in the case of peptone bouillon in which the presence of one or two bacilli will produce a reaction within 24 hours if other micro-organisms are excluded. In water containing the ordinary varieties of aquatic micro organisms the reaction is delayed unless comparatively large numbers of the bacillus coli communis are present Thus, if a cubic centimetre of unsterilised tap water, containing from 10 to 20 bacilli coli per cubic centimetre, were mixed with the neutral red bouillon, a reaction would be present in 24 hours, but if the bacilli numbered only from three to four per cubic centimetre their presence might not be shown until the second day had been completed. By noting such differences in time as varying amounts of the water to be examined require, a fairly accurate idea of the proportions of the bacillus coli present can be gained By making shake cultures with one or two cubic centimetres of water in neutral red glucose agar, and incubating at 37° C for two or three days, the bacillus coli can be detected and can be readily isolated when present in extremely small numbers The reaction in broth has so far proved to be specific "In [illegible] under anaerobic conditions—the [illegible] maligni œdematis produce a [illegible] llus coli communis. Not- [illegible] the reaction in regard to [illegible] mmunis in water supplies [illegible] ntends to publish soon the results of his experiments more in detail.

London Hospital, E.

A NOTE ON THE CONCURRENCE OF MEASLES AND DIPHTHERIA

By J D Rawlings, M B Lond, &c,

Late House Physician, St Bartholomew's Hospital.

One or two cases of the somewhat unusual combination of measles and diphtheria having been recently published in The Lancet the notes of the following case which came into my hands in 1895 at St. Bartholomew's Hospital may interest some of your readers

The patient, a child, aged 13 months, was admitted into the hospital for laryngeal obstruction She was quite well till a week before, when she developed a cough This continued till the day of admission when it became croupy and the breathing was noisy. On the day before there were a little discharge from the nose and redness of the eyes There was no history of exposure to the infection of diphtheria Two children in the house where the patient lived had had measles a fortnight before The patient never had measles or any other illness On admission the child was not very ill and was not cyanosed The breathing was stridulous, but the signs of laryngeal obstruction were not very great—indeed, tracheotomy never became necessary. The respirations were 40 There was slight inspiratory recession of the lower costal cartilages and epigastrium; the sterno-mastoids and scaleni were working The temperature was 102 8° F and the pulse was 160, of smaller volume during inspiration than during expiration There was no rash. General dry bronchitis existed, but there were no signs of pneumonia There was nothing abnormal in the fauces and there was little or no enlargement of the glands at the angles of the jaw. The urine showed a thick cloud of albumin. There was very slight injection of the conjunctivæ The diagnosis was important as I had to decide at once whether to admit the child to the diphtheria ward or not I decided to do so On the next morning the child had a measles rash, and the pathologist reported that diphtheria bacilli had grown from the swab The little patient died three days after admission Post mortem, flakes of diphtheritic membrane were found in the larynx and trachea and there was extensive broncho-pneumonia in both lungs

The case is interesting chiefly from the point of view of diagnosis The recognition of the diphtheria was due to the quantity of albumin in the urine and to the fact that the signs of laryngeal obstruction, although not great, were more than are generally found in the catarrh of uncomplicated measles These mixed cases of measles and diphtheria in young children are almost always fatal, and I think Mr. W Wyllys is to be congratulated on the favourable result in the case which he has published[1]

ST. MARY'S HOSPITAL.

A CASE OF SUBPHRENIC AND SPLENIC ABSCESS; OPERATION; RECOVERY

(Under the care of Dr. W. B Cheadle and Mr H Stansfield Collier)

The etiology of sub diaphragmatic abscesses is frequently very obscure, but it is fairly certain that in most of the cases the abscess is connected with a perforation of the stomach, duodenum, or some other portion of the bowel Dr Lee Dickinson in a paper read before the Pathological Society in 1895[2] referred to a case of subphrenic abscess which resulted from a duodenal ulcer Occasionally it may follow an appendicitis, but the abscess then is generally on the left side of the body For the notes of the case we are indebted to Dr H J Van Praagh, house physician

A domestic servant, aged 19 years, was admitted into the Alexandra Ward of St Mary's Hospital on Oct. 20th, 1900, under the care of Dr Cheadle, suffering from pain in the chest and shortness of breath. The patient had been quite well on the 18th, but on the evening of that date, whilst stooping at her work she was suddenly seized with pain in the left side which gradually grew worse until she was compelled to take to her bed. On the following day she had pain between the shoulders, across the chest, and down the left side; she was feverish and perspired considerably; she did not vomit, nor did she complain of pain in the abdomen. At this time she was seen by a medical man who found that she was suffering from pleurisy and sent her to the hospital. The personal history showed that two years previously she had suffered from pain after food, with occasional vomiting, but no hæmatemesis. She had had no dyspeptic symptoms recently.

---

[1] The Lancet, March 2nd, 1901, p 613.

[1] The Lancet, Feb. 23rd, 1901, p. 549.

[2] The Lancet, April 6th, 1895, p. 574.

On admission the patient was dyspnœic and complained of pain in the left side, which was made worse by breathing deeply. The temperature was 102° F., the pulse was 144, and the respirations were 36. On examination there were signs of consolidation at the base of the left lung, accompanied by a considerable amount of pleurisy. There was also fluid in the left pleural cavity, the heart being displaced two finger-breadths to the right. On abdominal examination the stomach was found to be somewhat dilated; the edge of the spleen was not palpable. There was no evidence of peritonitis, nor was there anything in the physical signs to suggest the presence of a gastric ulcer. The patient had been for some time past the subject of constipation. The heart-sounds were normal and very frequent. The urine was normal.

For the first week in the hospital there was no improvement in the condition of the patient, the pulse-rate remaining high, ranging from 110 to 136, and the pyrexia increasing until on Oct. 27th it attained to 104°. The physical signs did not vary from those present at the time of the admission of the patient to the hospital, except that there seemed to be evidence of the presence of a greater quantity of fluid in the left pleural cavity. As she became much more dyspnœic paracentesis pleuræ (mid-axillary line, sixth space) was performed and 20 ounces of clear fluid were withdrawn. With the removal of the fluid the dyspnœa became less, the temperature chart showing a fall from 104° to 100°, but the physical examination of the left chest did not show any diminution in the extent of the dulness and the tubular breathing became much louder than before. The temperature now went up again, the patient's general condition becoming worse, the pyrexia being of a remittent character accompanied by profuse sweating. On Nov. 3rd, at 6 P.M. the temperature rose to 104 8° and the pulse to 150, although the signs of consolidation were becoming less marked. The patient's condition was so strongly suggestive of suppuration that an exploring needle was introduced into the position of greatest dulness, which was in the tenth space, in the posterior scapular line, and some fœtid pus was evacuated.

Mr. H. Stansfield Collier, who was called by Dr. Cheadle to see the case, decided on immediate operation. The patient was anæsthetised with chloroform and the pus having been once more located by means of an exploratory needle an incision was made along the lower border of the eighth rib and a portion of the ninth rib was resected, when on inserting a director about two ounces of very foul pus flowed out. As there was some doubt as to the site of the abscess cavity the incision was prolonged backwards for about two inches and more rib was excised. After this the pus was found to come from beneath the diaphragm, especially from a cavity in the spleen substance, the director having traversed the muscular attachments of the diaphragm. The pleural cavity was also found to contain a few ounces of clear fluid which were drawn off. A large drainage-tube was inserted and the patient was put back to bed. For some days after the operation the temperature ranged between 101° and 105° and the pulse ran constantly up to 150; the wound remained in an extremely septic condition, the walls of the cavity being lined with grey sloughs. The pus was very foul, and it was found that the diaphragm, which had been stitched up to the thoracic wall during the operation, had given way, forming a communication between the pleural and abscess cavities. It was found necessary to have a tube draining each cavity, the wound being gently washed out twice daily with weak iodine solution, after which sloughs came away and the wound commenced to granulate.

The patient's condition still remained very critical, and a highly stimulant treatment was found necessary. For the next ten days the general toxæmic symptoms showed no signs of abatement, and on the evening of Nov. 14th, after the wound had been dressed, she was seized with a sudden violent pain in the right side, causing a syncopal attack of great severity. There was a loud friction rub to be heard all over the base of the right chest; an ice bag was applied and the friction rub disappeared in the course of ten days. There were never at any time any physical signs to suggest the presence of fluid. The patient seemed to get worse every day, excepting that she took all her nourishment exceedingly well and kept in remarkably good spirits. On the evening of Nov. 16th, she appeared to get much worse, being very dyspnœic and cyanosed. She had a rigor, the temperature at the time being 102·5°, and the pulse 190 and very small. During the night she had frequent inhalations of oxygen; champagne and brandy were given by the mouth, and strychnine was hypodermically injected. She gradually recovered from that time, having no further rigors and the toxæmic manifestations slowly retrograding. The local condition of the wound daily improved, and after several weeks of careful nursing and dieting, the temperature became normal, the pulse-rate and general condition corresponding favourably. For the last two or three weeks she had been taking ordinary food, and got up for the greater part of the day. The wound is closed except for a very small sinus, the left lung is expanding rapidly, and in the course of a few days the patient will be able to leave the hospital.

Remarks by Dr. VAN PRAAGH.—This case presents many points of exceptional interest. Splenic abscess is by no means a common condition, and it is stated to be most frequently caused by a perforation of a gastric or intestinal ulcer; in this case there was nothing either in the history, the symptoms, or the physical signs to suggest the presence of either; nor was there any local sepsis, adjacent or remote, which could have acted as an exciting cause. The diagnosis was rendered difficult in that the presence of fluid and consolidation at the base of the left chest appeared quite sufficient to account for the symptoms observed. The small size of the abscess rendered it exceedingly difficult of detection and the convalescence was much prolonged by the sloughing of the diaphragm, which caused the abscess cavity to come into direct communication with the pleural cavity. A notable point in the case was the extreme foulness of the abscess, and on account of this the cavity was irrigated with iodine solution and, I feel sure, with marked benefit. The slough separated and the cavity became much cleaner after this was done. The patient's symptoms were extremely acute after the operation, the pulse-rate especially being a great source of apprehension; it seldom went below 150 and I often counted it 180. There was also evidence of infection on the right side, but no fluid collected and the extensive friction rub disappeared within ten days. As regards the medical treatment of the case it consisted in the free use of stimulants and unremitting attention from the nurses.

I have to thank Dr. Cheadle and Mr. Collier for permission to publish this case.

BEDFORD COUNTY HOSPITAL.

TWO CASES OF SUPPURATIVE APPENDICITIS WITH SEPTICÆMIA; RECOVERY OF ONE PATIENT AFTER THE USE OF ANTI-STREPTOCOCCIC SERUM.

(Under the care of Mr. W. GIFFORD NASH.)

EACH of the following two cases illustrates well the extensive septic infection that may occur in appendicitis. In the first case a septic phlebitis occurred in some of the radicles of the mesenteric veins and the infected emboli from these gave rise to the pyæmic abscesses in the liver. In the second case the chief septic complications of the appendicitis were local abscesses. The administration of anti-streptococcic serum in this second case was followed by the recovery of the patient, but data are wanting to enable us to determine whether the serum was active in bringing about this recovery. Anti-streptococcic serum may be administered in cases of true septicæmia—that is to say, cases in which the streptococci have entered the blood-stream or in cases in which only sapræmia is present, when only the products of the organisms have been absorbed. In the latter group of cases it is very doubtful if any improvement could be looked for after the injection of anti-streptococcic serum, as the serum has no effect on the toxins. In cases of true septicæmia before we can expect any benefit from the use of the serum it should be ascertained that streptococci are present in the blood. For if the septicæmia is due to staphylococci no benefit can be expected from the serum. The difficulty of judging the value of the serum is much increased by the fact that there are several varieties of streptococci, each of which requires a special serum. On the whole, the experience of the few years which have passed since the introduction of the serum has not led to a very high opinion as to its value, though in a few cases striking results have followed. For the elucidation of the true value of the serum we need more cases in which it has been employed after a careful bacteriological examination of the blood.

CASE 1. *Appendicitis; abscess; incision; death from hepatic abscess.*—A girl, aged 19 years, was admitted to the Bedford County Hospital on July 21st, 1900, with a history that six days previously she had eaten a large quantity of unripe gooseberries and the following day had a severe attack of abdominal pain with diarrhœa and sickness She kept her bed for three days and then got up, but was forced by a return of pain to go back to bed Mr. Nash was then called to see her, and finding that she had a temperature of 105° F. and appendicitis sent her into hospital. On admission she complained of pain in the abdomen and in the lower part of the back There was tenderness on pressure over the right iliac fossa and a swelling of the size of the palm of the hand was made out by palpation. This was dull on percussion. The temperature was 104°, the tongue was very coated, and marked thirst was present Operation was performed on July 22nd. An incision about three inches long was made over the swelling below and to the outer side of the cæcum. The peritoneum lining the iliac fossa was much thickened and through a softened spot near the apex of the cæcum an abscess was opened containing several ounces of fœtid, brown pus. The appendix, which no doubt was buried in adhesions, was not seen and no prolonged search was made. The pus appeared to have burrowed between the visceral layer of the peritoneum covering the caput cæci and the muscular coat, forming a sort of pocket. The wound was irrigated with perchloride of mercury lotion and a drainage-tube was inserted and packed around with cyanide gauze. For two days after the operation there was some improvement, but on the 25th the temperature rose to 105·8°. On the 26th and 27th there were two rises from the base line to 105°, each rise being accompanied by a rigor. Large doses of quinine were given without any effect. On the 29th the wound was explored with the finger and a concretion was removed which doubtless had formed in the appendix. On the 30th, Mr. Nash being away, the case was handed over to Dr. H. Skelding One or two rigors continued to occur daily and on August 7th the temperature reached 107°. On the 8th Dr. Skelding enlarged the wound as it was feared there might be a collection of pus unable to drain. Another concretion was found but no pus was discovered. From the 9th to the 16th the rigors continued, the temperature ranging up to 105° or 107°, and the pulse from 100 to 140. There were tenderness over the area of the liver and pain referred to the region of the right shoulder The patient gradually became worse and died on August 18th.

Necropsy.—At the post-mortem examination the appendix was found to be surrounded by adhesions and if there had been an aperture it had now closed. The liver was found to be riddled with abscesses varying from the size of a pea to the size of a small orange. An abscess about two and a half inches in diameter was situated in the centre of the right lobe. These cavities contained green putrid offensive pus The spleen was enlarged and contained a few small pyæmic abscesses in its substance. The mesenteric glands were enlarged, fluctuating, and easily broken down, and were found to be infiltrated with pus.

CASE 2. *Appendicitis; abscess; incision; use of anti-streptococcic serum; recovery.*—A girl, aged 17 years, was seized with colicky pains in the abdomen on Sept 14th, 1900 This was accompanied by diarrhœa and vomiting. Four days later the pain was localised to the right iliac fossa During this time she had all the signs of pyrexia. Mr. Nash saw her and sent her into hospital. On admission on Sept. 21st, 1900, her temperature was 102° F., she had general abdominal pain, with a tender lump in the right iliac fossa Mr. Nash on the day after admission made a three-inch incision to the outer side of McBurney's point over the swelling and opened up a localised circumscribed abscess which discharged about a pint of dark yellow offensive pus; a counter opening was made at the outer border of the erector spinæ muscle and a drainage-tube was inserted, connecting it with the first incision; another tube was put into the anterior wound; a fæcal concretion of about the size of a hazel-nut was removed. The patient's condition improved after the operation, the wounds and cavity were syringed out twice daily with sanitas solution, and until the seventh day after the operation the temperature did not rise above 100°. After that daily rises to 102° were common. On Oct 11th Mr. Nash explored the wound under ether. There was no retention of pus in the abscess cavity. As there was tenderness on pressing over the ascending colon in the loin an incision was made exposing the colon and kidney, but no pus was found. This wound closed at once superficially, but pus formed in its depths and had to be evacuated later. Mr. Nash then thought that anti-streptococcic serum should be tried and 10 cubic centimetres of Burroughs and Wellcome's serum were injected twice daily. This did not actually lower the temperature at the time, but an extra secretion of pus occurred The anterior and lumbar wounds for some time previously having looked dry and unhealthy were discharging very little, and on some days no, pus. An examination of the blood on this date showed an excess of leucocytes. 20 cubic centimetres of anti-streptococcic serum were given daily from the day after the second operation for six days. The temperature fell to nearer the base line and did not rise above 100° until 12 days later, when it rose to 102°. On this day fluctuation was made out in the line of the lumbar incision which was closed. This was opened by a probe and dark foul-smelling pus was discharged. A tube was inserted This pocket of pus did not communicate with the other openings Her temperature then fell to 99° and did not rise above this until 11 days later, when it went up to 101·5°; at this time a fluctuating area was discovered above, and internal to, the other lumbar incision and near the middle line of the back, the pus having burrowed upwards This was opened and found to be connected with the cavity opened last by a very narrow sinus; it contained pus similar to that found at the last exploration. After this the patient improved steadily and her temperature did not rise above 99° During the illness brandy, quinine, and nutrients were given freely, and on Jan. 12th, 1901, she was discharged well after the wounds had healed

Remarks by MR. NASH—In THE LANCET of March 24th, 1900, p 852 was published a case of mine in which death occurred from hepatic abscess due to appendicitis In that case the suppuration in the liver was due to direct infection from pus tracking up behind the ascending colon In the case now recorded the infection was probably carried by the portal vein In the second case, although very free drainage was provided, septicæmia occurred. It is impossible to prove that the anti streptococcic serum did any good, but my opinion is that without it the patient would have died. In neither case was any attempt made to remove the appendix It is doubtful whether, if we had done so, the septicæmia would have been averted, as in the first case at the post mortem examination the appendix had so far recovered that the site of the perforation was not found, showing that there could not have been any sloughing.

Medical Societies.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY—A clinical meeting of this society was held on March 27th, Dr Gordon Black, the President, being in the chair.—Dr. B. J Hellier showed a patient on whom he had performed Conservative Cæsarean Section in November, 1900;[1] partial salpingectomy was performed at the same time The patient was in excellent health Menstruation was quite normal and there was no dysmenorrhœa The child had thriven very well—Mr. B. G. A. Moynihan showed a series of Stomach Operations: (1) Gastroplication performed three and a half years ago; (2) Gastro-gastrostomy and Gastroplasty for hour glass stomach; (3) Pyloroplasty for pyloric stenosis; (4) Gastro-enterostomy for simple and malignant disease; and (5) Gastrostomy.—Dr. T. Browne Hearder showed a married woman, aged 35 years, suffering from Raynaud's Disease—the stage of local asphyxia The duration had been for three months. There were no cardiac disease, no hæmoglobinuria, and no enlargement of the thyroid. She was improving under administrations of suprarenal tabloids.—Dr. E. Ward showed: (1) Hemithyroidectomy, rapid shrinking of the remaining half of the thyroid gland; (2) Gastro enterostomy, skiagram showing Murphy's button at the cardiac end of the stomach; and (3) Tendon Lengthening, partial relapse.—Dr. C. M. Chadwick showed: (1) Disseminating Sclerosis without Nystagmus; and (2) Paralysis Agitans with an Interesting History of Commencement.—Mr. W. H. Brown showed: (1) An Endosteal Tumour of the Os Frontis; (2) a Vesical Calculus from a boy, suprapubic lithotomy; (3) Plastic Operation for Ectopia Vesicæ; and (4) a Cephalic Meningocele.—Mr. Herbert J. Robson showed a case of Fracture of the Lower Jaw in an Edentulous Subject. The patient was 46 years of age. The fracture was at the junction of the left inner third with the outer two-thirds. The cause was direct violence. The patient was seen with Mr. Littlewood Young who made splints out of the artificial plates which were locked together, holes being made in the front and the sides for feeding and syringing purposes. Perfect union occurred at the end of four weeks.—Mr. A. L. Whitehead showed (1) a case from which a Rodent Ulcer involving half the lower eyelid had been removed 12 months previously, and in which a plastic operation had been performed for the restoration of the lid; (2) a case of Nævus of the Upper and Lower Eyelids in which repeated electrolysis having failed to effect a cure complete excision was performed with no subsequent deformity; (3) a case of Albuminuric Neuro-Retinitis; and (4) a case of Partial Detachment of the Retina following a localised cyclitis.—Dr. T. Wardrop Griffith showed: 1. A characteristic case of Acromegaly in a woman who had been under observation about seven years. 2. A woman, aged 32 years, who had been the subject of Laryngeal Fistula, the result of tertiary syphilitic changes. The fistula passed through the lower part of the thyroid cartilage, and there was extensive ulceration of the mucous membrane below the true vocal cords. The fistula had healed, and the ulceration was clearing up under iodide of potassium. 3 A young man, aged 19 years, who for upwards of two years had been the subject of Carpopedal Contractions of the "tetany" type. These had varied very much in severity but during the whole time the patient presented the facial phenomenon usually known as Chvostek's symptom.—Mr. Lawford Knaggs showed a patient nine months after Double Vasectomy for Prostatic Enlargement and Retention.—Mr. Mayo Robson and Mr. Lawford Knaggs showed a man, aged 84 years, who had been admitted to hospital in October with Prostatic Retention, and catheterism becoming impossible suprapubic cystotomy was performed and the prostate was felt to project into the bladder. For some time he was very feeble and in December double vasectomy was performed under cocaine. He was now in very good condition and was able to pass urine by the urethra every two hours. He had been re-admitted for another attack of retention induced by cold, but this had been completely relieved by a hot bath.—Dr. E. F. Trevelyan showed: 1. Two cases of Chronic Chorea, one in a girl, aged 20 years, and the other in a man, aged 50 years. The disease had lasted 14 and 20 years respectively. The movements were of the jerking purposeless type and were especially marked in the girl. There were no cardiac murmur in either case and no history of rheumatism. 2 A case of Graves's Disease in a man, aged 35 years, who had been under observation for seven years. His present condition was much the same now as it was then. The exophthalmos was more marked on the right side 3 A woman, aged 36 years, with Mitral Stenosis, who had recovered from a characteristic embolic hemiplegia. There was only a slight clumsiness in some of the fine movements of the fingers remaining. 4. Two cases of Cutaneous Syphilis, one with an extensive rupial eruption which improved rapidly under mercurial inunction.

---

[1] Brit. Med. Jour., Jan. 5th, 1901.

HUNTERIAN SOCIETY.—A meeting of this society was held on March 27th, Dr. J. Dundas Grant, the President, being in the chair.—Dr. W. H. Kelson read a paper on Some Affections of the Four Tonsils, touching chiefly on points in regard to which errors of diagnosis and treatment were common. Mycosis, herpes, and syphilis of the tonsils and its three stages were discussed, and the supra-tonsillar fossa with its diseases was described, with special reference to the work of Dr. D. R. Paterson. The various operations for reduction in size or removal of the faucial and post-nasal tonsils were reviewed and criticised, and the best methods of dealing with hæmorrhage and other complications were referred to. It was shown that hard substances were present in the tonsils, chiefly under three heads: (1) foreign bodies, (2) hardened, inspissated masses of secretion known as calculi, and (3) cartilaginous or bony nodules, thought by some to be vestigial remains derived from the second branchial arch. Malignant disease was touched upon and the great importance of its early recognition was shown. Affections of the lingual tonsil and the different views held as to the symptoms that might be thereby produced were described. The diseases of the four tonsils were finally considered collectively and comparatively as regards age and sex—also the likelihood of these acting as centres or points of origin for tuberculous infection, and their close relationship to rheumatism, gout, septic infection, and the fevers.—Dr. Fortescue Fox suggested that the occurrence of acute tonsillitis at the beginning of acute rheumatism might indicate the point of admission of the infective agent. He pointed out the infrequent association between gout and chronic follicular tonsillitis.—Mr. John Adams referred to the difficulty of diagnosis of syphilides on the tonsils alone. He had never seen a primary sore upon the tonsils and only one sarcoma of the tonsils —Mr. Francis Humphreys remarked upon a possible causal association between appendicitis and tonsillitis; these often occurred together. He referred to some cases of apparently commencing rheumatic fever that had been cut short by applications to the tonsils —Dr. W. J. McC. Ettles said that he had found the application of sulphurous acid and glycerine effective in the treatment of pharyngeal mycosis and salicylate of soda in acute tonsillitis.—Dr. Carson referred to the occasional existence of a bleeding point high up in the tonsil in cases of obstinate bleeding from the throat. Persistent bleeding after removal of tonsils never occurred if the patient was allowed to rest after the operation.—The President said that it was very often best to neglect pharyngo-mycosis as a disease of little consequence and tedious to treat. He referred to cases of great pain in the throat with only slight morbid appearances in influenza. A mixture of 10 per cent menthol, 10 per cent. guaiacol, and 80 per cent. olive oil was an effective application in tonsillitis. Tonsils were like open wounds so far as infection went; nurses sometimes became infected from the feeding-bottles of syphilitic children. An enlarged tonsil sometimes blocked up the entrance to the supra-tonsillar fossa. Removal of the pharyngeal tonsil sometimes should be carried out through the anterior nares. Enlargement of the lingual tonsil sometimes caused gre[illegible]ess when it touched the epiglottis. In bleeding after t[illegible]ny some recommended lying down, some sitting up.

DERMATOLOG[illegible]IETY OF GREAT BRITAIN AND IRELAND.—A meeti[illegible] of the above society was held at 20, Hanover-square, London, W., on March 27th, Dr. A. J. Harrison, the President, being in the chair, when the following cases were shown. Dr. William T. Freeman showed a Mottled Erythema of the Legs resembling "erythema ab igne" but with no history of exposure to heat.—Dr. P. S. Abraham brought forward (1) a Malay who had been supposed to be the subject of Elephantiasis Græcorum. The man had several cicatrices on the thighs, but these had possibly resulted from an attack of plague from which he had suffered. (2) A girl of about 12 years of age, with an Exuberant Congenital Linear Papillomatous Growth extending from the chin in the median line of the neck to below the thyroid body. With regard to the first of the two cases Dr. Abraham thought that the diagnosis must remain indefinite.—Dr. Alfred Eddowes showed a case of Lupus Erythematosus beginning in the follicles —Mr. Arthur Shillitoe brought forward a man of middle age suffering from an extensive Pustular Dermatitis of the Legs and Thighs.—The President was inclined to think that its origin was syphilitic.—Several members considered that the use of strong ointments, with which the man had been treating himself, had aggravated an initial eczema into the formidable folliculitis now present.—Dr. J. H. Stowers advised the use of sedative lotions and in particular the avoidance of any greasy applications.—Mr. George Pernet showed (for Dr Radcliffe Crocker) (1) a boy, aged four years, with an acute attack, dating from a fortnight previously, of Prurigo of Hebra (Dr. Crocker spoke in support of this diagnosis and considered that the alternative, urticaria papulosa, was negatived by the distribution and type of the lesions); and (2) a young woman with a large Keloid of the Arm which had benefited under continued injections with thiosinamine.—Dr. J. Herbert Stowers brought forward a woman suffering from Bazin's Disease of unusual distribution.—Dr. Graham Little showed a case of Chronic Acne Scrofulosorum in a child, aged 12 years. Giant cells but no tubercle bacilli had been found in sections of an excised pustule.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held at the Kidderminster Infirmary on March 29th, Mr. J. Lionel Stretton, the President, being in the chair.—The secretary announced that as a result of a conference between a sub-committee of the society and a deputation from the Stourport Medical Association the association had amended its rules so that in future: (1) the association would confine its membership solely to the *bonâ-fide* wage-earning classes; (2) canvassing for members would be prohibited; and (3) the capital would not exceed £100 In consideration of these amendments the disabilities which had been imposed upon their medical officer were removed.[1]—The President showed (1) a large Cyst of the size of a bantam's egg removed from the verge of the anus of a man, aged 48 years; and (2) an Appendix Cæci removed from a woman, aged 25 years. She was seized with acute symptoms on a Friday night after a hearty meal. The medical attendant was called in on the Sunday, when he found that the patient was suffering from appendicitis with some [illegible] consultation it was decided [illegible] was done by the usual incision [illegible] pint of milky pus and some fæ[illegible] perforation was found near the root of the appendix from which fæcal matter was flowing freely; the tip, which was fully six inches away and was also perforated, was fixed *posteriorly*. It was ligatured and removed and the abdomen was swabbed out with sterilised gauze, a strip being left in, and the wound was closed with silkworm gut sutures On the following day the pulse was 98 and the temperature was normal.—The President remarked on the great length of the appendix, the fact that there were two perforations, and the remarkable recovery in spite of the large amount of peritonitis and constitutional disturbance. He insisted on the importance of dry swabbing as opposed to flushing.—Dr. Evans read notes of a case of Strangulated Hernia upon which he had operated.

CARDIFF MEDICAL SOCIETY.—The ordinary monthly meeting of this society was held on March 1st, Dr. E. Walford, the President, being in the chair.—The minutes of the last two meetings were read and confirmed.—Dr. W. Mitchell Stevens sent for the acceptance of the society a Ross's Eclipse Microscope which had been purchased through the subscriptions of several members and the heartiest thanks of the society were given to Dr Stevens.—The President read a letter from Mr. Edmund Owen cordially accepting the committee's invitation to give the annual address in June.—Dr. Herbert G. G. Cook showed a specimen of a Tumour of the Breast removed six days previously. The history of the case was one of from eight to nine years' duration with rapid increase of growth latterly. The diagnosis lay between sarcoma, carcinoma, and tubercle Microscopical examination proved it to be carcinomatous.—Mr. William Sheen showed an Arm amputated for Recurrent Sarcoma A mass of infected axillary glands were also removed and the axillary artery was compressed through this wound while the arm was amputated.—Mr. J. Lynn Thomas related his experiences with the Welsh Hospital in South Africa, illustrating his remarks by lantern-slides of Springfontein, Bloemfontein, and Pretoria Mr. Thomas also showed slides of the different forms of missiles used in the campaign and gave his general impressions of the surgery of the war.—The President expressed the thanks of the society to Mr. Thomas for his communication.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—At a meeting of this society on April 4th, Dr. E S Yonge (Manchester) gave a demonstration on the Methods of Examining the Larynx, Trachea, and Œsophagus in Adults and Children. Useful hints were given as regards the use of the laryngoscope in difficult cases and exceptional methods were referred to. A large number of instruments were shown and their use was demonstrated on patients.—In replying to a vote of thanks Dr. Yonge, in response to a suggestion, made some remarks on the Diagnosis of Post-nasal Adenoids.

Reviews and Notices of Books.

Student's Edition: a Practical Treatise of Materia Medica and Therapeutics, with special reference to the Clinical Application of Drugs. By JOHN V. SHOEMAKER, M.D., LL D., Professor of Materia Medica, Pharmacology, and Therapeutics in the Medico-Chirurgical College of Philadelphia. Fifth edition. Philadelphia: F. A Davis Company. Pp vii-770. Extra cloth, $4 00 net.

THE present edition marks a curious result of the rapid growth of new remedies. The author has decided to divide his well-known work into two independent issues, adapted respectively to the requirements of students and physicians. In this volume, which is intended for students, attention is limited to the drugs and preparations which are official in the Pharmacopœias of the United States and Great Britain. Whether the forthcoming Physicians' Edition will consist solely of unofficial remedies or will include such remedies in addition to the material in the present volume is not yet disclosed. The Students' Edition will be found sufficiently comprehensive for ordinary purposes and it contains many references to unofficial drugs which are "chemical modifications" of those within the pale.

The book is divided into two parts In the first the author deals briefly with general considerations concerning remedies and systems of treatment, with prescription-writing and formulæ, and with poisons and antidotes, together with other cognate matters. The second part consists of a single section, nearly 650 pages in length, relating to official remedies or drugs contained in the United States and British Pharmacopœias English readers will find the first part of little service as, for example, in the pharmaceutical classes of remedies, attention is concentrated on the United States Pharmacopœia and the result is somewhat bewildering Thus 88 fluid extracts are enumerated, whilst the list of pills falls far short of that in the British Pharmacopœia. On the other hand, all that relates to prescription-writing and formulæ may be studied with pleasure and profit, and under this heading will be found valuable lists of drugs which form explosive compounds, of those forming unsightly and undesirable mixtures, and of those which are physiologically incompatible.

With regard to the second part it may be doubted whether the alphabetical order is best adapted for a student's text-book It facilitates reference, but it appears to suggest that the volume is not to be studied as a whole. We should have preferred to have had the drugs grouped according to their leading therapeutic actions which would favour comparison and selection, leaving the index to save the time and trouble of the more advanced student who desires to refresh his memory rapidly

The author has evidently taken great pains with the revision of this edition as he includes references to numerous recent contributions to the literature of official remedies Each drug has separate sections relating to its definition, its preparations, its pharmacology, its toxicology (with appropriate antidotes), and its therapeutic actions, with suggestions as to eligible forms of administration. The term "pharmacology," although defined in the earlier pages, is used in several different senses; sometimes (see p 77) it includes only the physical and chemical properties, and physiological action is dealt with in a separate section, while on a previous page (see p 75) under the same heading there are descriptions of physiological actions and of toxic effects, while the term "toxicology" only embraces the treatment of the latter. For the use of senior students such occasional lapses are perhaps of small moment when compared with the amount of information included under the name of each drug. The numerous prescriptions on almost every page will be found suggestive and useful. As a whole, however, notwithstanding its title, this edition appears likely to be more serviceable as a book of reference for the busy practitioner than as a text-book for students. Although everyone derives benefit from consulting a dictionary few would be bold enough to attempt to study it page by page.

The City of London Directory for 1901. Including a Streets Guide, Alphabetical Directory, Trades Guide, Livery Companies Guide, List of Liverymen Voters, a Biographical Directory, Corporation Directory, Public Companies Directory, and also a Coloured Map of the City of London. The thirty-first annual edition. London: W. H. & L. Collingridge. Pp. 1222. Price 12*s.* 6*d.*

The first edition of the "City of London Directory" published in the twentieth century and in the first year of the reign of His Most Gracious Majesty King Edward VII. is the thirty-first annual issue of this publication. The edition contains much exclusive information in regard to the corporation, the livery companies, the charities, the clubs, the officers and administrative departments, the schools, and the commercial circles of the City of London. The official section contains a complete list of the aldermen and members of the Court of Common Council, with full details of the officials connected with the various executive bodies of the City. A list of the mayors, aldermen, and councillors of the new borough councils is a feature of the work. Lists are given of the members of the Court of Lieutenancy, the London County Council, the London School Board, and the City of London Union. Particulars of the city churches appear, together with a list of the clergy and a statement as to the value of their benefices. The educational advantages and opportunities which the city schools afford to all classes are described, and particulars of all these schools are given with reliable information as to fees and scholarships and numerous historical details. The streets section has been carefully revised, all the occupiers whose names appear having been canvassed to ensure accuracy. The alphabetical list contains the name, address, and trade or profession of every person, and, as far as can be ascertained, of each individual member of firms in the City of London. The names are classified again as a trades guide under the various trades or professions. The street improvements of the year are indicated in a large coloured map, and include all recent alterations. The Central London Railway is shown as a line in use, and the Great Northern and City Railway as a line in course of construction. The boundaries of the wards and parishes are accurately marked, the former being clearly indicated in colour; and ready reference is facilitated to every street and turning in "the one square mile."

The directory is a valuable book of reference which finds a place as a matter of course on the shelves of most business men residing in, or closely connected with, the City of London.

Medico-Surgical Aspects of the Spanish-American War. By Dr. NICHOLAS SENN, Chief Surgeon, U.S. Volunteers. Chicago: American Medical Association Press. 1900. Pp. 380.

This book is apparently a collection of papers and letters contributed to various journals, and this being so, it is not written upon any definitely coherent plan. However, it gives a series of very striking pictures of the work of an army surgeon in war-time. There is a passage on page 10 which reads oddly in the light of present events and may be paralleled by our own case in South Africa. "The hero of Manilla has planted the Stars and Stripes, the emblem of liberty and equality, on the shores of the distant Philippine Islands; there it will remain until the unhappy inhabitants breathe the bracing air of independence." The inhabitants at present, however, seem to be as incredulous of the blessings of the rule of the Great Republic as are the Boers of the blessings of British rule. One of the most interesting sections in the book is that entitled, "Recent Experiences in Military Surgery after the Battle of Santiago." With regard to wounds inflicted by the small-calibre jacketed bullet it was noticed that where the wounds were infected it was more often at the wound of exit than at that of entry, a fact which Dr. Senn explains by the larger size of the wound and the greater laceration of the tissues. Dr. Senn lays stress upon what has been noticed over and over again in South Africa—that more attention must be paid to the value of the first dressing; and he recommends that in every first-dressing package a packet of antiseptic powder should be supplied. He prefers a combination of boric and salicylic acids in the proportion of four to one. The use of the *x* rays was found to be very valuable in the location of projectiles. Penetrating gunshot wounds of the abdomen healed in many cases without surgical interference and Dr. Senn quotes one remarkable instance. A soldier received an injury while lying in the prone position, the bullet entering the left infra-spinous fossa and passing downwards and inwards until it lodged under the skin in the median line, two inches above the umbilicus. The patient had a good deal of hæmoptysis for two days. An abscess formed in the abdominal wall, which was opened 18 days after the injury and the bullet was removed. After this rapid improvement occurred.

The section dealing with "The Qualifications and Duties of the Military Surgeon" is excellent reading. We have perused it with both pleasure and profit, and we expect those of our readers who are interested in the subject—and who is not at the present time?—will do the same. The chapter is, we think, sensible, practical, and full of good points. Lieutenant-Colonel Nicholas Senn, as chief surgeon of the United States Volunteers and chief of the operating staff with the army in the field, had good opportunities for seeing the work done by the surgeons of the regular army of the United States and those of the National Guard. War is the most searching test of field medical systems and methods for these speedily arrange themselves upon the sides of right and wrong, workable and unworkable. It is because this fact, although only just touched upon by the author, is nevertheless recognised in a wholesome and straightforward spirit that we read what he has to say with gratification.

LIBRARY TABLE.

The Thompson-Yates Laboratories Reports. Edited by RUBERT BOYCE and C. S. SHERRINGTON. Vol. III., Part II. Liverpool: At the University Press. 1901. Pp. 266. Price 5*s.* 6*d.* net.—This book is beautifully got up in the accustomed style of the Liverpool University Press. Nearly half the book is taken up by the third memoir of the Liverpool School of Tropical Medicine, being Part I. of the Malaria Expedition to Nigeria. Among the other papers are an obituary notice of the late Dr. Walter Myers, a paper by Dr. S. R. Christophers on the Prevention of Malaria in Tropical Africa, and one on the Life-history of the Parasites of Malaria, by Major Ronald Ross and Dr. R. Fielding-Ould.

Encyklopadie der Gesammten Chirurgie. (*Encyclopædia of General Surgery.*) Edited by Professor THEODOR KOCHER and Dr. F. DE QUERVAIN. Leipzig: F. C. W. Vogel. 1901. Part I. Aachen—Angioma. Large 8vo. Pp. 48. Price 2 marks.—This surgical dictionary, alphabetically arranged, and well printed in double columns in a large page, is expected to be completed in 25 parts at 2 marks each. The list of contributors is a long one, containing many eminent names, and to judge from Part I., which terminates with Angioma, the work promises well. Some of the principal articles, each of about three pages, are Abscess, by Dr.

Buchbinder of Leipzig; Achselhöhle, by Professor Zuckerkandl of Vienna and Dr. Bardenheuer of Cologne; Adnexerkrankungen, by Dr H. W. Freund of Strassburg; Aether, by Dr. Dumont of Bern; Alkohol, by Dr. F. de Quervain of La Chaux-de-Fonds, one of the editors; and Amputation, by Dr. Dumont Several illustrations are inserted in the text.

Another English Woman's Love Letters. By BARRY PAIN. London: T. Fisher Unwin. 1901. Pp. 142 Price 2*s* — Most persons have by this time read the much talked about "Love Letters of an English Woman," that clever picture of a morbid, introspective, and much-to-be-pitied woman who gave herself heart and soul to an insufferable "bounder" who posed as an honourable gentleman and sent the woman who loved him "his kind regards" when she lay on her death bed. We owe a great debt of gratitude to the author, whoever he be, seeing that he has been the cause of Mr. Barry Pain giving to the world the delightful little book now before us. Despite the east winds, a rising income-tax, and the census, the other Englishwoman has given us cause for many a laugh The therapeutics of laughter are well known and we recommend our readers first to peruse the book themselves and then to tell their patients to do the same The Italian portion of the letters is inimitable.

The Clincher Guide Cycling Routes of England and Wales. With a Map. By T. A. EDGE London: Walter Scott, Limited. 1901. Price 1*s*.—In this little book the roads of England and Wales are tabulated in a series of routes and all towns are indexed The mileage, including a description of the surface and the contour of the roads, is also indicated by means of easily remembered letters and symbols. On the map numbers are placed which correspond with the various series of routes and by the aid of the ample index it is a simple matter for a cyclist to trace the best way to take between any two given towns. We are not aware of any book which gives so much useful information in a form so easy for reference and so cheap.

JOURNALS.

Edinburgh Medical Journal —The first of the original communications in the April number is an article on Light and Colour Perception, by Dr. F. W Edridge-Green, an outline of whose views on the subject will be found in THE LANCET of May 26th, 1900 (p. 1511), August 4th, 1900 (p 323), and in another column of the present number (p 1077). He considers that the solar spectrum may be divided into six bands, each of which is monochromatic so far as visual perception is concerned, because no person looking at such an isolated band could tell which edge of it was directed either to the red or to the blue end of the spectrum. It is of course well known that the wave lengths in every part of the spectrum undergo progressive alteration, but persons with ordinary normal vision can recognise only six distinct colours—namely, red, orange, yellow, green, blue, and violet Colour-blindness, he says, is due to the widening of one or more of these bands, so that as the length of the natural spectrum remains the same the number of the bands becomes reduced. In the first degree of colour-blindness five instead of six colours are seen, orange having disappeared In the next degree only four colours are seen, blue having disappeared. After blue it is yellow which disappears In the next degree of colour-blindness only two colours are seen, green having disappeared. Those who see only two colours in the spectrum confuse red, orange, yellow, and green on the one hand and blue green, blue, and violet on the other. He considers that colour-blindness should be tested, not by matching different colours, such as coloured wools, but by naming the colours. Two papers are concluded in this number—namely, one on the Form of Crystals, by Dr. J. Bell Pettigrew, and one on Pernicious Anæmia, by Dr. Vincent Dickinson.

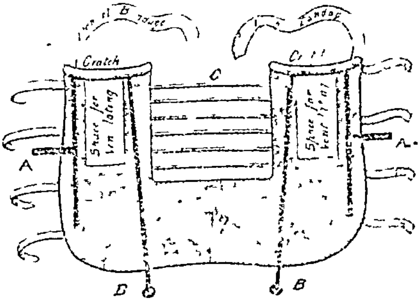
Caledonian Medical Journal —The April number opens with a Gaelic elegy on the death of Queen Victoria. In the editorial paragraphs it is announced that the Gunning Celtic Prizes have occasioned a considerable correspondence on the part of inquirers asking information from the secretary, Dr. S. R Macphail of Rowditch, Derby. Particulars of these prizes have already appeared in THE LANCET of Dec 8th (p 1658) and Dec 22nd (p. 1825), 1900, and Jan. 19th (p 191), 1901. The frontispiece shows the main block of the sanatorium for tuberculosis at Nordrach on-Dee, and the accompanying description states that there are many miles of specially laid out walks in the grounds of the sanatorium and in the surrounding forests. Dr. Alastair MacGregor of Shepley, Huddersfield, in bringing to a close his series of articles on "second sight," gives details of various instances of premonition of death by spectral apparitions and unaccountable noises, and Sir Arthur Mitchell of Edinburgh writes quoting from Aubrey's "Miscellanies" a passage to the effect that Harvey, the discoverer of the circulation of the blood, was saved from drowning in the Straits of Dover through the agency of a warning vision seen by the governor of Dover in a dream.

Mercy and Truth —In the April number Dr Martyn Clark writes on baptisms at Amritsar in the Punjab, and Dr. Howard Cook contributes an illustrated description of a visit to Toro in East Africa It is announced that the Archbishop of Canterbury will preside at the annual meeting of the Medical Mission Auxiliary in St. James's Hall on April 30th.

New Inventions.

JACKET FOR SPINAL CARIES AND ANGULAR CURVATURE.

I HAVE had this jacket made for the treatment of a case of angular curvature of the spine coming on in adult life and involving the eighth and ninth dorsal vertebræ After several months' confinement to his room the patient recovered so far that with the help of this jacket he was able to resume his occupation. The illustration shows the jacket as it would appear if flattened out and looked at from behind The shaded part is of leather—stout sole leather dipped for a minute or two in boiling water and moulded to the body by firm bandaging. The four thick black lines represent uprights made of bamboo or other strong light wood and fastened to the leather. The hinder pair (B B) extend below the leather and rest on the chair when the wearer sits



will be found suggestive and useful. As a whole, however, notwithstanding its title, this edition appears likely to be more serviceable as a book of reference for the busy practitioner than as a text-book for students. Although everyone derives benefit from consulting a dictionary few would be bold enough to attempt to study it page by page.

The City of London Directory for 1901. Edinburgh Medical Journal.—The first of the original communications in the April number is an article on Light and Colour Perception, by Dr. F. W. Edridge Green, an outline of whose views on the subject will be found in THE LANCET of May 26th, 1900 (p. 1511), August 4th, 1900 (p. 322), and in another column of the present number (p. 1077). He considers that the solar spectrum may be divided into six bands, each of which is monochromatic so far as visual perception is concerned, because no person looking at such an isolated band could tell which edge of it was directed either to the red or to the blue end of the spectrum. It is of course well known that the wave lengths in every part of the spectrum undergo progressive alteration, but persons with ordinary normal vision can recognise only six distinct colours—namely, red, orange, yellow, green, blue, and violet. Colour-blindness, he says, is due to the widening of one or more of these bands, so that as the length of the natural spectrum remains the same the number of the bands becomes reduced. In the first degree of colour-blindness five instead of six colours are seen, orange having disappeared. In the next degree only four colours are seen, blue having disappeared. After blue it is yellow which disappears. In the next degree of colour-blindness only two colours are seen, green having disappeared. Those who see only two colours in the spectrum confuse red, orange, yellow, and green on the one hand and blue-green, blue, and violet on the other. He considers that colour-blindness should be tested, not by matching different colours, such as coloured wools, but by naming the colours. Two papers are concluded in this number—namely, one on the Form of Crystals, by Dr. J. Bell Pettigrew, and one on Pernicious Anæmia, by Dr. Vincent Dickinson.

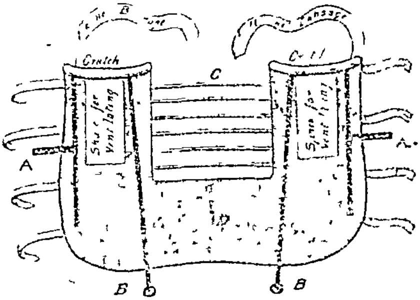
Caledonian Medical Journal.—The April number opens with a Gaelic elegy on the death of Queen Victoria. In the editorial paragraphs it is announced that the Gunning Celtic Prizes have occasioned a considerable correspondence on the part of inquirers asking information from the secretary, Dr. S. R. Macphail of Rowditch, Derby. Particulars of these prizes have already appeared in THE LANCET of Dec. 8th (p. 1658) and Dec. 22nd (p. 1825), 1900, and Jan. 19th (p. 191), 1901. The frontispiece shows the main block of the sanatorium for tuberculosis at Nordrach-on-Dee, and the accompanying description states that there are many miles of specially laid out walks in the grounds of the sanatorium and in the surrounding forests. Dr. Alastair MacGregor of Shepley, Huddersfield, in bringing to a close his series of articles on "second sight," gives details of various instances of premonition of death by spectral apparitions and unaccountable noises, and Sir Arthur Mitchell of Edinburgh writes quoting from Aubrey's "Miscellanies" a passage to the effect that Harvey, the discoverer of the circulation of the blood, was saved from drowning in the Straits of Dover through the agency of a warning vision seen by the governor of Dover in a dream.

Mercy and Truth.—In the April number Dr. Martyn Clark writes on baptisms at Amritsar in the Punjab, and Dr. Howard Cook contributes an illustrated description of a visit to Toro in East Africa. It is announced that the Archbishop of Canterbury will preside at the annual meeting of the Medical Mission Auxiliary in St. James's Hall on April 30th.

New Inventions.

JACKET FOR SPINAL CARIES AND ANGULAR CURVATURE.

I HAVE had this jacket made for the treatment of a case of angular curvature of the spine coming on in adult life and involving the eighth and ninth dorsal vertebræ. After several months' confinement to his room the patient recovered so far that with the help of this jacket he was able to resume his occupation. The illustration shows the jacket as it would appear if flattened out and looked at from behind. The shaded part is of leather—stout sole leather dipped for a minute or two in boiling water and moulded to the body by firm bandaging. The four thick black lines represent uprights made of bamboo or other strong light wood and fastened to the leather. The hinder pair (B B) extend below the leather and rest on the chair when the wearer sits



upright, thus giving a real support to the crutch in the axilla. To the front pair are attached two arm-rests (A A). These are of steel encased in thick leather and are when thus covered with leather about six inches long and an inch and a half wide. They revolve horizontally round a bit of steel attached to the bamboo, and are so made that they can be taken off easily. The jacket is in halves, jointed below over the sacrum with a leather hinge (D); above there is an open space (O) at the upper part of the back, across which loops of cane are tightly drawn to support the back. In front the jacket reaches barely to the anterior superior iliac spine on either side, and is held in place by leather straps across the abdomen. It should be well rounded off in front, or it will give pain on flexure of the thigh; and laterally it should reach to the great trochanters. There is a window on each side for coolness. A strap is carried across the front of the chest, not tightly for chest fixation, but to prevent the arms slipping forward over the front of the axillary crutches. If drawn tight this strap interferes with the breathing. I secure chest fixation and close adjustment of the upper part of the jacket to the body by carrying a loop of flannel bandage across each shoulder from the upper corner of the window of one side behind to that of the other side in front. This also checks the tendency of the jacket to slew round to the right with the movements of the body. The axillary crutch is made by bending over the edge of the leather on itself when moulding it to the body. On the top of this I fasten a bit of pneumatic bicycle tyre filled with water and tied with twine at both ends. This gives great comfort, for the support of this crutch is very real, and chafing is apt to result. The crutch must not be too thick or it will press against the inner side of the arm and give pain. The jacket is worn over the flannel shirt and drawers and the trousers are suspended from one of its straps. The waistcoat is slit up on either side over the anterior bamboo upright to let through the arm-rest. The arm-rest is covered and concealed by the coat-flap. Points in its favour are: (1) the arm-rests enable the weight of the upper part of the body to be swung through the shoulder from the elbows; (2) the posterior uprights resting on the seat give real support and are of special service, say, in pulling on boots or holding in a hard-mouthed pony; and (3) it is cool, cleanly, and efficient, and is easily made.

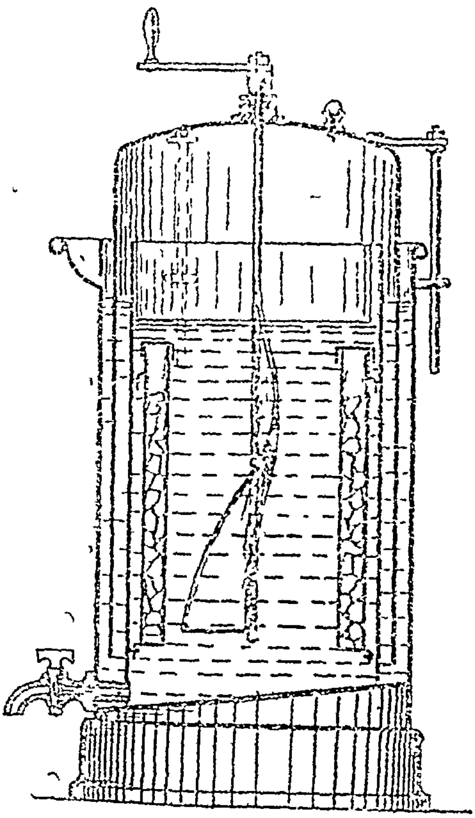
T. LAW GASKIN, M.R C S Eng , L R C.P. Edin.
St Michael's, Barbados, West Indies

THE "POISONING PREVENTER" LABEL.

THIS label has a vertical column of plainly-printed figures numbered from above downwards—say, from 1 to 12, corresponding to the successive doses of medicine contained in the bottle to which it is affixed. Opposite each of these figures there are spaces for writing down the hour and minute at which a dose is given. In this way many of the possibilities of error in the administration of medicines should be removed. The label is printed in various colours and measurements to suit standard bottles; and it is fixed on the narrower side of a bottle, with its marks to coincide with those on the bottle; or it can be used on a standard bottle which has no divisions. The label, which is patented, may be obtained from Mr. C. J. Whistler Hanson, 24, Harrington-square, London, N.W.

RECEPTACLE FOR MILK OR OTHER LIQUIDS.

THE illustration represents a new receptacle for holding milk or other liquids intended for human consumption. It is adapted for use alike in hospitals and in private houses, and is so constructed that the access of dust, flies, and other sources of contamination is entirely prevented, while at the same time the withdrawal of the contents is easy and cooling by means of ice is provided for. The apparatus is made of tinned sheet iron, zinc, copper, or earthenware. The cylindrical container has a double casing, with water in the annular space between the inner and the outer wall. Inside the container there are removeable tubular vessels which can be filled with ice when required; two of these are shown in the illustration. A cylindrical bell shaped cover dips into the water. A stirrer passing through the closed end of the bell and turned by means of a handle outside serves to mix the contents uniformly. When admission of air is required it is filtered by passing through sterilised felt contained in an air-tap outside the closed end of the bell. The receptacle is made in sizes to hold from a quart to 100 gallons. The patentee and manufacturer is Mr. W. T. Lawson, Hill Crest, Beech Lanes, Birmingham.



HEALTH OF ST. IVES.—Mr. J. M. Nicholls, the medical officer of health of St. Ives, Cornwall, in his annual report for 1900, states that the birth-rate was equal to 31·62 per 1000, as compared with 34·62 per 1000 in 1899. The death-rate was 18 67 per 1000, as compared with 15 75 per 1000 in 1899. Seven deaths were from zymotic diseases, including four from diphtheria and two from diarrhœa. The infant mortality was at the rate of 186 deaths per 1000 births. 49 cases of infectious diseases were notified, including eight of diphtheria, 10 of typhoid fever (in all of which the patients recovered), four of continued fever, and 22 of erysipelas.

HEALTH OF SIDMOUTH.—Dr. T. H. S. Pullin, the medical officer of health of Sidmouth, Devon, in his annual report for 1900 states that during the year the birth-rate was 17 per 1000. The death-rate, if the deaths of 12 visitors to the town be included, was 15·25 per 1000; excluding the visitors it was 12 25 per 1000. The zymotic death rate was *nil*, being the fifth consecutive year without a death from one of the zymotic diseases. Only one case of infectious disease (enteric fever) was notified during the 12 months, the disease having been contracted abroad. The previous case of enteric fever was notified one year previously, and Mr. Pullin adds that only one death from this disease has been registered in the district during the past 20 years.

THE LANCET.

LONDON: SATURDAY, APRIL 13, 1901.

The Sanitary Condition of Windsor.

WINDSOR furnishes an example of the fact that the light of public opinion is apt to beat in a fierce fashion about a throne. Since the days of the Conqueror the town has figured prominently in the annals of the nation, and there are indications that under King EDWARD VII. Windsor will not lose favour as a Royal residence. In years not long gone by many pages of THE LANCET have been devoted to a consideration of the sanitary maladministration of the Windsor Corporation, and more recently (in THE LANCET of Dec. 18th, 1900, p. 1591) we drew attention in a leading article to a report made by Dr. H. T. BULSTRODE, one of the medical inspectors of the Local Government Board, upon this same old theme. This report attracted no little attention in the lay press, and the town council of Windsor have, it appears, devoted many sittings, much time, and some abuse to its consideration. The report revealed a far from creditable state of affairs, but it is not now our intention to revert to it in this sense.

Whatever may have been the forces which have kept that report prominently before the town council—and in a case of this sort there are obviously many channels through which influence might have been exerted—it is a matter of much satisfaction to us to be able to record that the corporation have now faced the issue in a truly commendable spirit, and that they have apparently persuaded themselves that the true interests of the town of Windsor would best be served by putting their house in order. According to the *Windsor Chronicle* of March 22nd a special committee, which has for some months past been considering the answer which should be given to the Local Government Board report, have recently presented a draft of their conclusions to the corporation and a discussion which occupied some two and a half hours ensued. Some exception was taken to the fact that the introductory portion of the Government report went as far back as 1858, the council urging that the sins of the forefathers should not be visited upon the children, but Councillor BROWN PORTER disposed of this objection by the pointed remark, "There are forefathers present," implying, we gather, that all those who were of the council in 1858 have not even yet retired therefrom.

The report of the committee, as amended by the town council, shows signs of proving to be a very reasonable and healthy document. Action has been taken in respect of practically all the points raised in the inspector's report, and in the matter of the housing of the poor of Windsor it is gratifying to read that certain areas have been declared to be "unhealthy areas" within the meaning of the Housing of the Working Classes Acts. The surveyor has been instructed to prepare a scheme with a view to demolish the whole of the western side of River-street, a street which has for years figured prominently in the annals of Windsor, and to which many references will be found in our columns. Dwellings for the working-classes are to be erected on the site. Action is also apparently to be taken with respect to certain "obstructive buildings." As regards the sanitary condition of "Victoria cottages," the dwellings which through the complaint of Mr. STONEHAM of the Berkshire County Council were instrumental in bringing about the Local Government Board inquiry, it must be a source of much satisfaction to the inhabitants to know that "the whole of the roofs and ceilings have been put into a good state of repair." The by-laws and regulations are being rigorously enforced, and such as are out of date are to be modernised. The medical officer of health has been afforded free entry to the waterworks, and samples of water from the different wells are taken under his supervision for chemical and bacteriological examination. The change which has come over the spirit of administration in Windsor is indeed as remarkable as it must be welcome. In the words of the *Windsor Chronicle*, "For the condition of previous years the apathetic burgesses were largely responsible, but recently they have aroused themselves to return men to the council possessed with a real and serious desire to administer the affairs of the town for the general welfare."

In our view, too, no small amount of the improvement is due to the vigorous action of the local press and to the persistent support which they have accorded to sanitary reformers, such as Councillor RYLAND, who, if we may judge by the local reports, has for a long time occupied a position in the council of one crying in the wilderness. The advice, too, which was given by Councillor Sir J. SOUNDY that the council "would do their best to remedy the evils of the past" was well worthy of the support which it has received. It is clear that Dr. BULSTRODE'S report had effected good both to the town council as a public body as well as to the town as a whole, and we must ourselves confess to a feeling of satisfaction that the reforms which we have for so long advocated in these pages are now in a fair way to be carried into effect.

The Lettsomian Lectures.

THE subject chosen by Dr. MITCHELL BRUCE for the Lettsomian Lectures this year was Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life, and he has earned the thanks not only of the Medical Society of London but of the profession at large by selecting for consideration a matter which will interest all practitioners and by dealing with it in such a practical manner. Lectures and papers on the scientific aspect of disease are more frequent than those which deal with the more practical side, and these lectures will be welcomed accordingly as being the outcome of exceptional experience and close and careful study of the clinical material which has come before the lecturer in his private and hospital practice.

Dr. MITCHELL BRUCE'S subject will at once arrest attention, for the problem of disorders of the heart as set forth in the title of the lectures may be said to come before the family practitioner during every hour of his work, and to present difficulties and to create a sense of responsibility or even anxiety which cannot be over-estimated. The investigation of such cases forms an interesting study, and, as the lecturer rightly points out, the answer to the many questions which arise can be given only after an analysis of a considerable number of instances of the kind in respect of their origin, their clinical character and course, and the result. We further entirely agree with him when he says, "Our attention lately has been too much confined to the pathological states of the heart and arteries and too little directed to the causes which produce them." For instance, "arterial *sclerosis*" is an ordinary diagnosis in everyday practice, as if it were sufficient for purposes of prognosis and treatment to have determined that the radial artery is thicker, larger, and more dense than normal, without considering the actual nature of the pathological change, whether due to strain, syphilitic, gouty, or otherwise. The term "*dilatation of the heart*," also, is apt to be employed as if the enlargement of the cardiac chamber or chambers was a distinct disease rather than the result of varying morbid conditions.

Before considering the influences and circumstances which disorder or damage the circulation in middle and advanced life Dr. MITCHELL BRUCE drew attention to the normal or natural state of the heart and arteries after 40 years of age, and showed that as life advances certain changes take place which must not be *considered* as pathological, and that the term "vascular *degeneration*" applied to such processes is misleading. There are, however, many forces that threaten the heart and arteries which are peculiar to that period of life, such as physical stress, nervous influences, and disturbances of metabolism, including gout. These singly or conjointly may bring about such cardiovascular changes as may greatly affect the patient's general health and necessitate a remodelling of his mode of life. There can be no doubt that the last named (disturbances of metabolism) are by far the most potent factors concerned, at any rate amongst the middle and higher classes in this country. The period of life referred to frequently brings with it comparative relaxation from work and a disposition to substitute quiet or even passive for active exercise, and whilst the demands of growth and development in the alimentary system have greatly declined the pleasures of the table and ease generally are too often indulged in. The results are functional disorders of the liver, gout in regular or irregular forms, gravel, and the many associated disorders of the muscular, nervous, and other systems. From various causes, as Dr. MITCHELL BRUCE aptly points out, the arterial tension rises, consequently the heart-vessels and kidneys are kept under incessant strain and, like other organs working under strain in the gouty subject, they are the readiest to suffer. There are other causes which may arise to threaten the heart in this stage of life, such as syphilis, acute diseases, emphysema, and chronic Bright's disease; these are duly commented on in the lectures. Special stress was laid on the "tobacco-heart" and the heart in alcoholism. These were dwelt upon in order to bring home an important consideration which is apt to be overlooked in diagnosis and still more in treatment—namely, that whether in an ordinary senile heart or in a heart that is the seat of chronic valvular disease or in arterial degeneration something more than the pathological changes have in many instances to be regarded—usually some entirely adventitious disturbance which alone calls for treatment, such as indigestion, flatulence, worry, bronchial catarrh, or it may be free indulgence in tobacco, tea, or coffee. It will be within the experience of most practitioners to have attended patients suffering from a moderate degree of cardiac dilatation in whom the symptoms and characters of the pulse are out of proportion to the amount of disease as estimated by physical examination—in many such instances on inquiry excessive indulgence in tobacco will be admitted, and if this can be controlled general improvement will soon be manifested. Not only is this the case at the period of life alluded to by Dr. MITCHELL BRUCE, but in younger men also similar symptoms due to the same cause are met with. Many subalterns and yeomen who have been invalided home from Africa have found that former indulgence in cigarettes had rendered them less able to contend against the peculiarities of the South African climate and the excitements of a campaign than were their fellows who had been more *moderate in this respect*.

Dr. MITCHELL BRUCE'S remarks on prognosis and treatment will well repay careful perusal. In order to arrive at a correct understanding on these points as full and correct a diagnosis as possible is essential—a purely anatomical diagnosis is *insufficient*, but as far as possible the *etiology* of the conditions must be sought out. In order to ascertain this in addition to the onset and progress of the symptoms it will probably be necessary to inquire into the previous history of the patient from childhood upwards. We have not space to comment fully on his valuable hints as to the interpretation of cardiac murmurs and symptoms, or on the indications for treatment which he so clearly lays down. He points out that morbific influences can be more easily controlled than pathological processes can be altered, and, what is of equal or greater importance, a knowledge of the causes of disease often enables the practitioner to prevent what he could not possibly cure; therefore, in respect to treatment also etiology is all-important.

◆

The Primate and Medical Authority.

AMONG the present forces of the country must be reckoned the Primate. Even when we do not altogether agree with him, which we are glad to think does not often occur, we listen to him with the respect due to a man of fourscore years who displays unabated energy and an ever-green interest in human progress. It is a great thing for Christianity that the head of the Anglican Church should be so strong in his physical and intellectual equipment. We all know that the Primate is a rigid abstainer and that he uses his *great* position in the Church and in the State for the repression, not only of drunkenness, but of the drinking of alcohol in all forms. And whether he is addressing a popular meeting at a Church Congress or that most unemotional assembly the House of Lords he shows the courage of his opinions and by his personal force *does* much to secure a hearing where less distinguished or less able speakers would fail. Some may think that he would do more good by identifying himself with a less uncompromising set of opinions than those which he is known to hold, and by advocating a more practicable reform than the suppression of the trade in alcoholic drink. But it is a part of his enormous influence to be thorough.

Dr. TEMPLE made an interesting speech recently at the London Temperance Hospital in which he enunciated the principles on which he would proceed if overtaken by an illness which induced his physician to order him to take alcohol. He said that he was close upon 80 years of age and did not think that they would find many men of 80 years able to do such work as he did. Any man who achieves the age of 80 years, under conditions of health and activity, is right to congratulate himself on his vigour, but, of course, the Primate is too well informed not to know that many octogenarians as active as himself are not total abstainers. He went on to say—

> "He did not profess now that if he were in the hands of a physician and he ordered alcohol he would refuse to take it. If he did not trust his physician he would go to another, but physicians now were different from what they were. If the patient now said that he was a total abstainer the physician generally accommodated himself to the position and permitted him to remain a total abstainer. ...... The medical profession did not try to stop total abstinence by force and say they could not bring people to health without alcohol."

These words should be weighed by over-zealous abstainers. They imply that in the opinion of Dr. TEMPLE a trusted physician is to be trusted to prescribe alcohol. We should have been surprised if his Grace had given the sanction of his authority to any other doctrine, and we trust that his words will serve as a lesson to those extreme teetotalers who will not allow any value to the use of alcohol and who presume in disease to think their judgment better than that of their medical man.

The Primate's words should be weighed, too, by medical men, who should apply to the prescription of alcohol the same care which they apply to the prescription of digitalis or other drugs. The habitual use of alcohol may be right or wrong, but the authority of the physician must not be invoked for it when it has been merely prescribed in an emergency of disease. There are few intelligent teetotalers who will not, like the Archbishop, accept the authority of the physician in the question of alcohol. The acceptance will be based by them on faith and medical men will best preserve and promote the true use of alcohol by *studying it in all its bearings* in each *individual case* and by prescribing it with proper limitations of time and dose. In a sense most hospitals now are temperance hospitals, for the medical staffs of all of them are alive to the objections—medical, moral, and financial—to giving alcohol to hospital cases where it is not needed. Some of this change of view may be due to the influence of the London Temperance Hospital. But more of it is due, we venture to suggest, to a truer estimate of the scientific value of alcohol, to a comprehension of the possibility of dispensing with it advantageously in many of the cases of disease which occupy hospital beds, and to a growing desire on the part of medical men to use their authority in the promotion of wiser views among the ignorant and the poor.

Annotations.

"Ne quid nimis."

HELION: £200 PER CUBIC FOOT.

No one has ever suggested that helion, the element which until recently was thought to exist in the sun but which was discovered in the gases contained in certain minerals by Professor Ramsay, would be of any practical utility. At present, moreover, it is not likely to be, for it is the costliest of all elements. The method now being pursued for capturing this element in workable quantity shows that its separation and concentration involves an enormous expense and the helion obtained costs about £200 per cubic foot. The same amount of money would at the present time purchase over one million cubic feet of coal gas. The price of helion, therefore, at present is more than a million times that of coal gas. The element occurs in the gases evolved in the hot mineral springs at Bath, and, as our own analyses have shown, it *is associated with carbonic acid gas, oxygen, nitrogen, and* argon. Professor Dewar is engaged in collecting these gases in large quantity and separating the constituents by means of excessively low temperatures—that is, by freezing. As we have already announced, he has been able to liquefy helion by employing liquid hydrogen as the refrigerant. Doubtless the present costly research is being undertaken, amongst other things, in order to see whether helion can be solidified. To gain this result temperature will cease to play a part, for absolute zero will have to be reached. The work of investigation is carried on under great difficulty and it is not without its dangers. The intense dismay at losing, say, five cubic feet of gas just when success is promised may be imagined. Thus the destruction of the containing vessel during the experiments would mean £1000 irretrievably gone. But the true value of research as often resides in negative as in positive results.

THE MARCH OF CLEANLINESS.

FIFTY years ago, when the Great Exhibition in Hyde Park was about to open or had lately opened, the perennial jester *Mr. Punch* waxed very satirical at the expense of our continental visitors. In his opinion their corporeal cleanliness left much to be desired, and accordingly he endeavoured to induce a remedy by means of ridicule. One of John Leech's inimitable "cuts" which saw the light about that period represented a formidable row of washstands drawn up with military regularity at the border of a public thoroughfare, each washstand, with ewers and basins all complete, being under the charge of a resplendent flunkey who, towel over arm, was inviting all and sundry to wash and to be clean. "Hold! Alfonzo," exclaims a highly bestocked and grimy *foreigner as*, struck with amazement, he stops short to gaze at the unwonted spectacle, "what is it then, that machine over there?" "My faith," replies his friend, raising his shoulders to his ears and extending two conspicuously dirty palms, "it is truly a droll affair, but I do not know." *Mr. Punch's* wit was justifiable, but its objects might have retorted with a *tu quoque*. Fifty years ago our man-in-the-street was far from being the well and regularly washed individual that he now is. The matutinal "tub" had not as yet become the daily institution that the introduction of baths into second class modern houses has helped to render it; and amongst the well-dressed, and therefore respectable, members of the community there were many persons of both sexes who habitually neglected from one year's end to another the ablution of the covered portions of their bodies. But whatever may have been the condition of things on the continent with regard to corporeal cleanliness when the last century was passing middle age, it is quite clear that, thanks mainly to antisepticism, educated foreigners are nowadays fully alive to its importance. Writing in the *Archives de Médecine Navale* for January last Dr. Lassabatie expresses himself to the following effect with reference to an ambulant *lavabo* which he has had constructed for use in the wards of the naval hospital at Rochefort: "Clean hands being just as imperious a necessity in the dresser and nurse as in the operator the means of cleansing them should always be available with the least possible expenditure of time and trouble. All persons whose duty involves contact with patients, medical as well as surgical, should therefore be able to render their hands aseptic without being obliged to run backwards and forwards in search of the needful appliances." In constructing his *lavabo* Dr. Lassabatie's first thought was efficiency, but he was likewise in a measure governed by the inevitable question of expense. *Moveable washstands are turned out in abundance* by the purveyors of sanitary requisites, but since many of them are unsuitable for various reasons and all are costly the inventor was impelled to institute the present experiment, which has proved to be a complete success. The fact that from motives of economy the Rochefort appliance has been constructed of wood does certainly add considerably to its heaviness, not only actually but also in an æsthetic sense, but no doubt it will be possible to devise a similar article with a metal skeleton which will be far lighter and more elegant in appearance. Wherever practicable the woodwork has been protected by glass panels and great care and ingenuity have also been exhibited in avoiding the occurrence of nooks and corners where dust could accumulate and microbes find a lodgment. Each *lavabo* supports two 18-inch basins of an oval shape, and four glass receptacles for aseptic fluids, which can only be set flowing by pressure of the foot. There are no plugs or stop-cocks for use by the hand. The whole apparatus with its fittings, which include also ample accommodation for dressing materials, costs about £6 (150 francs). It is a firm and substantial structure, but can be moved about with great ease and also quite noiselessly. Dr. Lassabatie sums up the advantages of his invention in the following terms: "The mobility of all the shelves, the rounded framework and supports, from which all angles have been, so to speak, completely suppressed, the exceeding facility with which the different fittings—such as basins, soap-dishes, bottles, &c.—can be removed for cleansing purposes, all these points combine in the production of a convenient piece of surgical furniture which answers to every requirement of the most scrupulous cleanliness. Thanks to it the surgeon throughout the whole of his visit has close beside him all that he requires to render his hands aseptic, while at the same time he is able to assure himself that the success of his labours will not be jeopardised by neglectful students or attendants."

THE METROPOLITAN WATER-SUPPLY.

THE February report of the Water Examiner to the Local Government Board has recently been published. It consists, as usual, chiefly of matter supplied by the engineers and chemists of the water companies. Dr. T. E. Thorpe, the Government analyst, reports that the water supplied by the Kent Company was of great organic purity and that that supplied by the New River Company was of very good quality. The only samples of water of which full analyses were made were taken on Feb. 18th, when the amount of organic impurity was found to be greatest in the case of the water of the East London Company, which was more than five times greater than that of the Kent Company. The water derived from the Thames was of "fair quality" throughout the month. This is faint praise. The East London Company's water was "inferior to the Thames water." The processes of purification adopted by some of the metropolitan water companies are obviously inadequate.

THE DESIRABILITY OF SPECIAL HOSPITALS FOR HIP-JOINT DISEASE IN CHILDREN.

DR. GRANT ANDREW read a paper before the Pathological and Clinical Society of Glasgow last December, the main object of which was to impress on the medical profession of Glasgow the very urgent need there is for the establishment in that city of a special hospital for the treatment of disease of the hip-joint in children. There are few diseases in which neglect, while not leading immediately to death, will cause more prolonged misery and discomfort than tuberculous disease of the hip-joint, and there are few in which timely treatment will more fully repay the care of the surgeon. For a truly successful result time is needed. The joint must be kept at rest with the aid of suitable apparatus for weeks, for months, and sometimes even for years, until the tuberculous disease subsides and the joint returns more or less completely to its normal state. If the disease has lasted only a short time, complete rest for a few months may restore the hip-joint to perfect health and with free mobility in every direction. If the period during which the disease has acted be longer, longer also will be the time during which the joint must be kept at rest, and the recovery which ultimately ensues will be by no means so perfect as in a less advanced case. When a case occurs in a child belonging to a family which can supply him or her with adequate care and nursing satisfactory results can be obtained, but the disease is by far most common among the class of patients who attend the out-patient department of hospitals, and the home arrangements in these cases are nearly always utterly unsuitable for a child with disease of the hip-joint. However willing the mother may be, the limited accommodation and absence of appliances make it absolutely useless to attempt to undertake the treatment in such houses and under such conditions. Therefore the child's admission into a hospital becomes absolutely necessary. For the treatment of the disease, when the child has been admitted, there are two chief methods. When the operation of excision of joints was introduced, and especially after the powerful advocacy of Fergusson, the head of the femur was more and more frequently excised, often at an early stage of the disease. In a large proportion of the cases the tuberculous affection was indeed stayed, but often a comparatively useless limb was left, so that in many instances the patient was condemned to carry about for the rest of his life a limb which had been rendered valueless by the removal of the head of the femur and the consequent destruction of the hip-joint. It became slowly recognised by many that such results as these were only too frequent, and though it was found that excision in some cases was followed by a rapid recovery with a useful limb, yet on the whole the results were no better, and in many cases worse, than could be obtained by less energetic measures. Thus there arose a reaction against the indiscriminate practice of excision and a more rational, if more tedious, treatment by rest with extension received ever-increasing support. It was found that with prolonged rest a large proportion of the cases of hip disease would recover without any operative interference beyond the opening of an abscess, and if extension were combined with this prolonged rest the ultimate position of the limb was all that could be desired, even though the joint might be ankylosed. There was also a minimum of shortening. For this prolonged rest, however, the wards of a general hospital are by no means well suited. The pressure on the accommodation of these hospitals entirely negatives the devotion of a number of beds to such tedious cases as those with disease of the hip, and there is therefore in many cases a compulsion to adopt more energetic measures than would be employed if the surgeon could have felt justified in keeping the patient for an indefinite period in hospital. In London the feeling that these cases should have the opportunity of resting for prolonged periods gave rise to the establishment of the Alexandra Hospital for disease of the hip where a certain number of children can be admitted and where they are kept until the disease has subsided. In some instances the period during which the child is an in-patient must be measured by years. The demand for admission, however, far exceeds the accommodation available, and so the others are treated as out-patients and nurses from the hospital visit them at their homes to fix and to adjust the extension apparatus supplied to the patients. It is the establishment in Glasgow of such an institution as this that Dr. Andrew advocates and its value must be apparent to all who carefully study the subject. All that we have said as to the desirability of prolonged rest in hip disease applies equally to tuberculous disease of the vertebral column. In the case of that disease, also, the exigencies of space compel the surgeon to treat as an out-patient many a case which would have derived signal benefit from a more prolonged period of rest. Therefore for spinal caries also the establishment of institutions is desirable where the patient may remain until recovery occurs. If general hospitals could afford to devote a certain number of beds to these cases there would be no need for any new hospital, but as the accommodation in most hospitals is already insufficient for the needs of the urgent cases coming to them it is hopeless to expect that any beds can be set aside, and therefore the need of a special hospital for this purpose becomes evident. As both hip-joint disease and caries of the spine are nearly always tuberculous, any hospital intended specially for them should certainly be adapted for the open-air treatment of tuberculosis, and placed in a suitable position and suitably arranged and constructed. The centre of a large city is by no means an ideal situation for such a hospital; rather it should be placed in the open country. Managed in the right way such an institution can prove of incalculable value to the patients admitted into it and will assist in the general advancement of surgical knowledge.

ALCOHOL AND ITS EFFECTS UPON THE NERVOUS SYSTEM.

AN important discussion on this subject took place at the New York Academy of Medicine on March 7th last, when various eminent physicians recorded their observations and experiences. Dr. Charles L. Dana in introducing the subject regarded it both in its practical and scientific aspects. He based his observations on the careful study of 350 cases of alcoholism at the Bellevue Hospital. The most frequent form of alcoholism was periodical dipsomania and the next was pseudo-dipsomania. Over two-thirds of the total number of patients had begun to "drink" before the age of 20 years, and all of them before 30 years. "As a rule," said Dr. Dana, "the drunkard did not live more than 15 years, and it was seldom that the human organism could outlive more than 3000 intoxications." Death in alcoholics usually occurred from pneumonia, meningitis, delirium tremens, alcoholic insanity, or dementia. Dr. Herman Biggs stated that in 15 years the cases he had seen of drink were those resulting from indulgence in whisky and beer, the majority of patients taking two or three glasses of whisky and four or five pints of beer daily. In these cases cirrhosis of the liver was relatively less frequent, while the degenerative effects, such as disease of the heart, blood-vessels, and kidneys, were much more common. Looking over the records of the Health Department of New York he found a short time ago that whereas during 20 years the population had increased by from 50 to 60 per cent. the number of deaths recorded as due to degenerative diseases of the heart and blood-vessels—most frequently of alcoholic origin—had increased by nearly 150 per cent. and almost the same was true of renal disease. The excessive consumption of lager beer in the United States, as in Germany, produced renal disease and cerebral accidents. Professor M. Allen Starr said that of the various alcoholic beverages champagne produced exhilaration of spirits and stimulation of the flow of ideas, while Burgundy made a person think more slowly and by no means added to the feeling of conviviality. Alcohol seemed to affect the brain more than it did other parts of the nervous system. There was practically no known disease of the spinal cord produced by alcoholism, but both encephalopathy and peripheral neuritis were common. The pathology of alcoholic insanity was to day clear and characteristic. The researches of various observers, especially Andriezen and Berkley, showed that the alcoholic poison produced destruction of the epidendritic "gemmules" belonging to the nerve-cells of the brain, thus rendering the organ relatively incapable of receiving impulses, weakening reaction time, and producing loss of memory in general, features which were characteristic of nearly all forms of chronic alcoholism The neurasthenia of the chronic drunkard was dependent on degenerative changes in the protoplasm of his brain-cells. Such persons were little open to medical treatment but were more susceptible to social and religious influences. He was of opinion that "any measure of a religious or social character that could be brought to bear upon the individual was well worthy of trial. ..... The only reformed drunkards of whom he had knowledge were those who had been saved not through medical but through religious influence." Dr. Alexander Lambert pointed out the importance of heredity and quoted statistics to show the abnormally large proportion of defective and diseased children in the progeny of alcoholic parents. Dr. James Ewing referred to the pathological changes in the brain associated with alcoholic delirium tremens, and stated that the discoveries made by the aid of Golgi's and Nissl's methods demonstrated a close analogy to the brain lesions of sunstroke, tetanus, and hydrophobia. From necropsies made at various hospitals in New York it appeared that the visceral lesions of alcoholic origin were more prominent than those of tuberculosis or of syphilis. Dr. S. A. Knopf pointed out that alcoholism was a pronounced factor in predisposing towards tuberculosis. Statistics showed that 25 per cent. of children committed to sanatoria for tuberculous diseases had alcoholic parents. Dr. G. L. Peabody said that intemperance often arose from ignorance or from the want of a stimulant to relieve depression and fatigue after the day's work. Sherry wine was a flavoured spirit containing from 35 to 40 per cent. of alcohol, and many of the so-called "bitters" in the market recommended as a substitute for alcohol and as conducive to temperance contained from 40 to 50 per cent. of alcohol. This should be made known to ladies who took them under the misapprehension that they were non alcoholic beverages.

MILL-OWNERS AND RIVERS.

MR. JUSTICE DAY recently gave judgment in a case heard by him at Exeter which is of interest to those who view with consternation the pollution of our rivers, whether by domestic sewage or by the fouling incidental to certain manufactures. In Willcocks v. Hamlyn Brothers, the case referred to, the plaintiffs sought and obtained an injunction against the defendents for diminishing their supply of water. Both are mill-owners at Buckfastleigh, a small town in South Devon, situated on the Dart, some few miles above

Totnes, and also, of course, above Dartmouth. The defendants in the course of their manufacture fouled the river, and in connexion with a new sewerage scheme were requested by the sanitary authority to divert all water so polluted from the river, making use of the sewerage system for its disposal. This they did, but although by repairing an old leat they endeavoured to make good the amount of water thus taken from the river they failed to do so, and the plaintiffs, who needed a full supply of water as a motive power and for other purposes, complained. Mr. Justice Day in giving judgment approved, as he could hardly have failed to do, of the action of the sanitary authority in forbidding the return of polluted water to the stream, but at the same time declared the right of the riparian owners below the defendants to have their due supply of water undiminished. The result of this appears to be that manufacturers can be prevented from fouling rivers and that manufacturers so prevented who need a large quantity of water for the carrying on of their works must arrange matters so that they may obtain it without depriving others of that which they are entitled to have unimpaired both in quantity and quality. Very many persons besides the successful plaintiffs in the action to which we have called attention must be directly interested in the maintaining of the purity and the volume of the waters of the Dart at every point at which either can be assailed.

PRUS'S METHOD OF RESUSCITATION IN CHLOROFORM TOXÆMIA.

DR. FREYBERGER,[1] in *Treatment* for January, 1901, p. 785, gives a very interesting *résumé* of a method of which we as yet know very little. The patient upon whom it was tried was a labourer, aged 27 years, about to be operated upon for severe sciatica. He was presumably healthy. Chloroform was administered at 8 A.M. from an Esmarch's mask. Slight excitement was met with, but in 15 minutes complete anæsthesia, it is stated, was established; the pupils were contracted and the respiration was normal. However, when the incision over the sciatic nerve was made struggling occurred. This seems to point to the fact that "complete anæsthesia" at least was not present. More chloroform was given, but as soon as a few inhalations had been taken "asphyxia" developed. This was recovered from after the employment of tongue traction and artificial respiration. Four drachms of chloroform had up to this point been given and no more was subsequently used. The operation was proceeded with, but after a few minutes respiration again failed and this time the measures for resuscitation were unsuccessful in relieving the asphyxia. Ten minutes having been spent in fruitless attempts to resuscitate the patient the trachea was opened and air was blown into the lungs through an indiarubber tube. This measure was without effect. Prus's cardiac massage was then decided upon and was carried out in the following manner. An incision was made in the skin and muscles obliquely, the flap having its base in the left mammary line and its borders being parallel to the third and fifth ribs and left sternal edge. The third and fourth ribs were cut close to the sternum and two and a half inches were resected in the flap. In doing this the left pleural cavity had been accidentally opened. The hand was then introduced and the heart with the pericardium still intact was grasped. No heart movements were felt. Rhythmic compressions of the heart were systematically practised partly by grasping the viscus and partly by pressing it against the back of the sternum. After a short time slight spontaneous contractions were felt. The perflation of the lungs was maintained throughout. The spontaneous cardiac movements gradually increased, but no spontaneous respiration was initiated until half an hour after the artificial cardiac compression had been commenced. They were at first feeble and infrequent, and it was not until two and a half hours after the failure of respiration that the patient was able to take more than 10 consecutive respirations. At the end of three hours he was, however, breathing deeply and without effort. At this point both cardiac compression and artificial respiration were discontinued. He was absolutely unconscious and insensitive; all the wounds were sewn up and dressed without exciting any sign of consciousness or sense. Four hours from the commencement of the inhalation respiration became again difficult and after a few minutes completely ceased. The final phenomena of this most curious and, we believe, unique case are best given in Dr. Freyberger's own words: "From this until death—that is, from midday until 8 P.M.—he drew not a single breath, but his heart continued to beat with sustained force for more than seven hours before its strength began to fail." It was beating per minute. The patient throughout all this period did not regain consciousness. The pupils did not react to light and were contracted. The radial pulse was imperceptible all the time, but there was visible venous pulsation in the neck. It is stated that after the final respiratory failure the stomach and intestines became atonic and distended with gas and that "the intestinal odour" was detected in the air forced out of the lungs in the process of artificial respiration. The temperature of the body was fairly maintained, falling slightly; after eight hours it was 98° F. in the rectum and after 11½ hours 94°. Although every measure likely to restore respiration was tried all failed. The necropsy revealed that the right lung had firm adhesions to the chest wall, while there was pneumothorax on the left owing to the accidental wound in the pleura. A possible cause of death is suggested—viz., that owing to bad ventilation of the room the stove allowed phosgene gas to be formed from the chloroform (four drachms) which accumulated and poisoned the patient. In controversion of such a theory it must be remembered that it is well known that the operator, his assistants, and the nurses as a rule are more affected by this poison than is the patient, and in the case in point it is expressly stated that no one even noticed the suffocating fumes which are at once detected when phosgene gas is present in a room. Furthermore, the small quantity of chloroform evaporated renders this view highly improbable. The more likely cause seems to us to be the artificial pneumothorax resulting from the wound in the left pleura, which, associated with the adherent right lung, must have seriously interfered with respiration. Even this theory is not sufficient, for it appears that the respiratory movements were at fault rather than any mechanical impediment to the ventilation of the lungs, so that the medullary centre appears to have been practically rendered *hors de combat* four hours after the chloroform had ceased to be inhaled and never again to have reacted to the stimulus of perfused air which entered the lungs, and in spite of the fact that the heart was beating vigorously and automatically. It must be admitted that the case is one which defies explanation, while it affords hope that Prus's method may in suitable cases, and when resorted to earlier, restore life in cases of cardiac failure in chloroform toxæmia. The pneumothorax thus accidentally produced must be admitted to be at least an added danger, and Dr. Freyberger considers it as such, hence its avoidance in the operation required for the performance of Prus's plan of heart massage becomes a matter of great moment. Weber[2] has suggested, as Dr.

---

[2] Ueber eine neue Methode der Brustkorberöffnung zur Bloslegung des Herzens, Bericht über die Verhandlungen der Deutschen Gesellschaft für Chirurgie, Beilage zum Centralblatt für Chirurgie, 1899, Band xxvii.

Freyberger points out, a safer method of exposing the heart. He makes the following incision From the right edge of the sternum close to the insertion of the fourth rib cartilage an elliptical flap of skin and muscles is made across the sternum to the upper border of the corresponding rib on the left about a finger's breadth from the sternum. This is continued obliquely over the fourth, fifth, sixth, and seventh ribs, ending at the left costal margin. The sternum is sawn across at the level of the skin incision. The intercostals in the third space can be detached without injury to the intermammary artery. The cartilages of the fourth to the seventh ribs are cut from without inwards. The under surface of the flap being carefully freed the xiphoid is divided by a bone forceps and the flap is dissected up. It is worth noting that although normal saline solution was introduced after the final failure of respiration it was not employed in the earlier stages of the case. We think such a use of saline solution as soon as the heart's action is re established should be adopted in all cases in which a poison such as chloroform has been acting upon the nerve centres through the blood, as it certainly offers a chance of diluting the poison and of assisting the circulation. Although Prus's plan may appear heroic, yet it must be borne in mind that in the class of cases in which it is intended to be of use the danger is urgent and most grave and demands any measures, however severe, which appear to offer a reasonable chance of success.

REGULATION OF MARRIAGE IN MINNESOTA.

A MOST important problem that confronts the medical man and sanitarian is how to prevent as far as possible the perpetuation and increase of disease The sanitarian has been doing, and is doing, his part nobly in providing pure water, good drainage, and airy and well ventilated dwellings, with the result that the spread of certain maladies has been considerably checked. But unfortunately there is one—the most potent—means of disseminating disease which up to the present it has been found impossible to prevent. The marriage of diseased individuals is a very sure way of propagating and spreading a large number of deadly maladies. There can be no doubt that insanity, epilepsy, idiocy, tuberculosis, and syphilis would be very much less frequent were they not transmitted by the agency of marriage, and it would decidedly be for the welfare of the community at large if marriages between persons afflicted with any of these diseases could be hindered The facts are too notorious to need emphasising that the marriage of tuberculous individuals will result in the propagation of a progeny predisposed to the contraction of the same disease; that the union of those afflicted with epilepsy or idiocy, or who have been insane, will increase and spread these conditions to a lamentable extent; that gonorrhœa is responsible for a large proportion of women's pelvic troubles; and that syphilis is the greatest cause of abortions and still-births, besides contaminating and rendering weakly the offspring of those infected with its poison. The difficulty is to decide what steps to take to restrain marriages between persons thus affected. In Great Britain public sentiment is doubtless too strong against prohibitive legislation to anticipate any such drastic measures being enforced. In the United States, however, a large number of laymen and medical practitioners throughout the country are altogether favourably disposed to the regulation of marriages by the State Already several Bills have been introduced into different States with this end in view. North Dakota in February, 1899, passed a Bill to regulate marriage. Under this law no licence to marry is granted unless the applicants present a certificate from a board of examining physicians that they are free from infectious venereal diseases Michigan passed a law in 1899 making it a felony for any person with uncured syphilis to marry. Into the legislatures of other States resolutions have been introduced providing that persons desirous of being married must produce a medical certificate testifying to their sound health before the ceremony can be performed. But the most sweeping Bill of this description as yet brought forward is that of Minnesota This Bill, which passed the Senate of that State on March 23rd, is proposed as a measure to restrict the marriage of persons afflicted with mental or physical disorders. The measure is said to be reasonably certain to become law, and while it is aimed at the class above-named it will affect all those seeking marriage, inasmuch as a physical examination of the candidates for matrimony is a *sine quâ non.* The Bill provides that no man or woman who is epileptic, imbecile, feeble minded, or afflicted with chronic insanity shall intermarry within the State when the woman is under the age of 45 years. Any person who, not being an epileptic, marries an imbecile or one afflicted with chronic insanity or who knowingly violates this provision shall upon conviction be punished by a fine of not more than $1000 (£200) or by imprisonment in the State prison for not more than five years or by both such fine and imprisonment. Marriage licences cannot be issued unless accompanied by a certificate from a reputable physician testifying to the health of candidates for matrimony, and so far as can be judged to their good family history. The great increase in the number of inmates in the insane and imbecile asylums of Minnesota affords the strongest argument in favour of the passage of this Bill. Of course, it is more than doubtful if legislation of this nature will be found workable, and its desirability is also open to doubt. The argument of those who uphold prohibitive legislation to restrict marriages between the unfit is that some State must make a start and that if the remedy is successful others will quickly follow. The experiment of Minnesota will be watched with interest. But the old difficulty of squelching the promptings of animal nature is ever with us—"Naturam expellas furca, tamen usque recurret" And there is danger in too grandmotherly legislation.

DYSBASIA INTERMITTENS ANGIOSCLEROTICA (INTERMITTENT LAMENESS OF VASCULAR ORIGIN).

IN the *Boston Medical and Surgical Journal* of Feb. 21st Dr. James J. Putnam has published a case of this rare condition, which was first described by Charcot in 1854 and subsequently investigated by Goldflam and Erb. The subjects are persons usually past middle life After walking for from five to ten minutes they are seized with a helpless cramp-like feeling in the legs which is so severe as to render further progress impossible. After a few moments' rest they can walk again. Careful examination of the legs usually reveals signs of defective arterial supply. One or more of the pedal arteries, and even the popliteal arteries, may be pulseless, and the foot, as a consequence, cool and slightly pale, or red, or blue, according to circumstances As dysbasia intermittens sometimes occurs when the arteries are apparently pervious vasomotor spasm has also been suggested a a cause. In Charcot's first case a tumour was found compressing the popliteal artery. The occurrence of the symptoms during exertion may be due to the need of the muscles for an increased supply of blood or to the induction of vascular spasm. The disorder is chronic Considerable improvement may sometimes be produced by measures which tend to promote the circulation—iodide of potassium, warmth, prolonged galvanism with the feet resting in warm water, and cardiac tonics. An active business man, aged 70 years, came under Dr. Putnam's care. His history was exceedingly good and he showed no signs of visceral disease.

Two months previously he began to suffer from intense pain and a sense of fatigue in the legs every time he walked more than one eighth of a mile. On resting the symptoms quickly passed away. The pain was usually felt first in the left calf, then in the right, then it spread upwards omitting the knees and becoming centred in the hips, when he was compelled to stop. The heart was normal. Pulsation could be felt in only two of the four pedal arteries, and in one of these it was scarcely recognisable. Galvanism and faradaism were applied to the lower limbs while the legs were immersed in warm water, but no improvement was obtained. The patient then took to kneading his calves night and morning and began to improve. Ultimately he could walk one or even two miles without much difficulty.

THE MARTYRED PRIMROSE.

It is probably too late for this season to stay the wholesale destruction which is annually carried on in the home of the primrose. No flower is more truly native or expressive in our lowland rural scenery than this lowly gem. None is more dear to the dweller in these islands. And yet every spring witnesses cartloads, not of flowers but of whole plants, dug out of their green pastoral setting and carried to the metropolis to languish awhile in window-boxes and smoke haunted gardens and then too often to die. It is well to preserve the memory of illustrious persons and well also to adorn the grey sobriety of towns with livelier hues, but surely not at so great a sacrifice as this. Cut flowers will best fulfil the former purpose, and if it be desirable to decorate our public parks and suburban gardens this object can most properly be attained by following some intelligent and regulated method. If the present systemless havoc be allowed full licence we are likely to find that our rustic fields, which have hitherto been flower-spangled after nature's own chaste and lavish taste, are become barren of that grace. Legislation has stepped in to protect wild animal life, with the result that species once in danger of extermination have begun to thrive again. Cannot something be done by the same means and by the local resolve of county councils and landowners to prevent this barbarous uprooting of the primrose by trading collectors?

INFECTION WITH BALANTIDIUM COLI.

In the February number of the *Bulletin of the Johns Hopkins Hospital*, Dr. Richard P. Strong and Dr. W. E. Musgrave of the United States army in Manila described a case of infection with balantidium coli (Stein). This organism, they say, was probably first observed by Leeuwenhoek. Malsten, in 1857, in Stockholm, first described the parasite in a patient who suffered from painful diarrhœa. A great number of the parasites were found in the intestinal mucus and fæces, and the condition of the patient improved considerably as they decreased in number. The patient observed by Dr. Strong and Dr. Musgrave went to the Philippine Islands in December, 1899. He was perfectly well until April, 1900, when he began to have diarrhœa which continually grew worse. He entered the hospital on June 9th, and from that date up to the time of his death on August 11th he had continuous uncontrollable diarrhœa. The stools showed large numbers of flagellate infusoria, measuring from 70μ to 110μ long by 60μ to 72μ broad. The periphery was covered with fine actively motile cilia. An ectosarc and endosarc could be distinguished, and the parasite possessed the power of changing its shape. For some days before death each portion of the patient's fæces placed beneath a cover-glass contained between 100 and 200 of these infusoria. At the necropsy the mucosa of the large intestine was found to be covered with bloody mucus, beneath which the mucosa itself was very much reddened and contained a number of shallow ulcerations. Dr. Strong and Dr. Musgrave regarded the parasite as the exciting cause of the diarrhœa.

LEICESTER AND HYDROPATHY.

Some years ago[1] we commented upon the action of the Leicester Board of Guardians who tried to induce their medical officer to allow a Mr. Pickering to experiment upon the paupers under treatment in the workhouse infirmary for fever. Mr. Pickering is the exponent of a hydropathic treatment, but the medical officer, naturally enough, declined to allow the experiment—a decision which seems to have hurt the feelings of the guardians. The advocates of hydropathy are, however, to use a sporting phrase, "still going strong," and they have seized upon the opportunity afforded by the resignation of Mr. H. G. H. Monk, who was medical superintendent of the isolation hospital, to ventilate their fad afresh. The question of the appointment of a temporary medical officer was debated by the Sanitary Committee on April 3rd, but we are glad to see that the water-cure faddists' nominee was beaten by a small majority. Leicester is an odd place. If the hydropathists are so anxious to promulgate their fancy why do they not try it on themselves and not on unfortunate paupers? The present medical officer is Mr. H. R. Hancock, and we have no doubt that he will not have the slightest hesitation in ordering a patient a bath if in his opinion the patient requires one. But this is not enough for the hydropathists.

"BACTERIOLOGY AND THE MERCHANDISE MARKS ACT."

Adverting to an annotation in The Lancet of April 6th, p 1030, under the above heading, a correspondent who writes as a tobacco expert, while interested in the possibility of bacteria being turned to account in the production of fine flavours, "would point out our error of description" in this connexion. He says, and this is of course well known, that Havana produces varieties of tobacco (of flavour and texture), and he asks "if the specific microbe could be of any service why does not nature retain its original course and perfect the plants in the combined and normal environment?" He adds that "surely no plea of [a similar] environment can be considered as possible existing between the Neckarthal district or even Alsace compared with Havana" He rightly assumes that no well-informed person will deny the progressive inferiority of the Havana cigar and he asks, Is this due to the depreciation of the tobacco, the presence of the microbe, or the depreciation of the microbe? Of course, bacteria do not produce tobacco, but tobacco is nothing without being fermented and in the process of fermentation definite organisms are concerned. The bacteria produce changes in the carbohydrates, vegetable acids, and in the nicotine, evolving new substances which add very materially to the flavour and aroma of the tobacco. In the same way yeast organisms produce from grape juice an alcoholic fluid containing new substances, whence the bouquet, which make it wine. We are not referring to probabilities but to actual well-established bacteriological facts. Havana bacteria have been isolated which differ from those of the German "weed" and the inoculation of the latter with Havana bacteria has resulted in a greatly improved flavour. The analogy to wine, again, holds, for wines are improved by the inoculation of the grape juice with specific pure yeast. Of course, much depends upon the quality of the original article. As to the deterioration of the Havana cigar, even that may find explanation in bacteriological facts: the cultivation may be at fault or the soil impoverished, so that the leaf is poor in substance and unfavourable to the development of the special bacteria during fermentation which have much to do with the production of flavour and aroma. The quality of hay depends largely upon fermentation produced by a specific thermogenic organism by the operations of which the hay acquires its peculiar aromatic odour.

THE PROSECUTION OF T. R. ALLINSON.

WE are glad to see that the police, who certainly do not move precipitately in such matters, have struck a blow at the trade in obscene literature sold under the guise of "medical works," by bringing T. R. Allinson, ex-L.R C.P. Edin., before the magistrate at the Marylebone Police-court. The result of the proceedings was that two of the summonses were adjourned *sine die*, the defendant being bound over in £250 to come up for judgment if called upon, an obligation which should act as a restraint upon his future operations; while under a third summons a large quantity of printed beastliness was ordered to be destroyed forthwith, Mr. Curtis Bennett remarking that he had read the pamphlets and that nothing more filthy could possibly have been written, and that they contained as much filth as could be compressed into a given space. The pernicious nature of Allinson's trade will have been realised by those who read that these pamphlets, sold as advice to married women, were sent to a detective who inclosed payment and described himself as a girl, 17 years of age, who had just left school, and who gave an address at a newsagent's. While congratulating the public and the medical profession on the result of this prosecution we cannot congratulate the police on their vigilance or their zeal. The trade of Allinson was not unique. We printed recently a list of books and pamphlets appearing under the title "Medical Works" in the advertisement columns of the *People*. A glance at these will show that there are others besides Allinson whose trade might well be inquired into.

INFANT MORTALITY IN RUSSIA.

SOME remarkable figures relative to infant mortality in Russia are published in the *Novosti* of March 26th, based upon statistics compiled by the Central Statistical Committee (probably with Government help) and summarised by Dr. Nikiteno. For great natural increase of population Russia stands well among the first of European countries, the birth-rate being from 37 to 46 per 1000; but unfortunately this great annual growth does not show markedly owing to the high death-rate among young children. The mortality in towns is much less than among the peasantry. Only 732 infants out of every 1000 born survive their first year. According to the returns for 1897, out of a population of 95,215,415 in the 50 governments of European Russia the number of deaths was as follows: children up to one year, 1,196,674; children up to five years, 1,858,850; children up to 15 years, 2,100,757; and adults, 991,044. According to the medical department, the deaths of infants from 1887 to 1892 were annually about 385,000 from Asiatic cholera alone. By dividing Russia into two "belts"—the north-eastern with 27 governments and the south-western with 23—detailed examination is facilitated. In the north-eastern belt for the four years 1893–1896 there died 3,242,065 children out of 10,037,287 born, while in the south-western belt the deaths were 1,544,632 out of 7,826,679 born. In the north-eastern belt there are some districts where more than half the children born never survive their [illegible] has risen to 626 per 1[illegible] chiefly to irregular [illegible] peasant families. In the Ufimsky, Kasansky, and Orenburgsky districts, where Mahomedans are in the majority, the infantile mortality is distinctly less.

THE TRAFFIC IN OLD HORSES.

ON March 30th a man was fined at the Thames Police-court £3 and £1 11*s.* 6*d.* costs under the Cruelty to Animals Act for leading a horse which was very lame and in pain. The horse was going to be shipped on board the Rotterdam boat. We pointed out some time ago[1] that an order had been issued by the Board of Agriculture by which, from Jan. 1st, 1899, it should be unlawful to convey from any port in the British Isles to any place outside the British Isles "any horse which, owing to age, infirmity, illness, fatigue, or any other reason cannot be so conveyed without cruelty during the intended passage and upon landing." Offences under this order were to be dealt with as under the Diseases of Animals Act, 1894. By this Act anyone offending against its provisions shall be liable to a fine not exceeding £20, or if the offence be committed with respect to more than one animal to a fine of not exceeding £5 for each animal. We have not, however, seen reported a single case where punishment has been inflicted under the Diseases of Animals Act and the Order of the Board of Agriculture, and we should be glad to know why magistrates and others do not use the powers to which they are entitled. As we have said over and over again, the traffic in old worn-out horses is a disgrace to this country. It should be stopped altogether, but pending a regulation to this effect the abominable trade should be made as expensive as possible, so that those who carry it on should be made to feel that it does not pay. Apart from the cruelty involved, even if people like to eat the flesh of diseased and worn-out animals it is no reason why we, as a nation, should make money out of pandering to such a taste.

HÆMORRHAGE FROM TONSILLAR ABSCESS.

HÆMORRHAGE from a tonsillar abscess is so rare that the following case published in the *New York Medical Journal* in March by Dr. W. F. Chappell is of interest. A man, aged 27 years, had two attacks of quinsy in the past two years, each resulting in an abscess which had to be opened. A third attack began on Dec. 1st, 1899, with great pain in the right side of the throat, extending down the neck. He was under treatment for five weeks, during which time four incisions were made with little relief. He then went to the hospital with great swelling of the neck, which was evident both internally and externally, and an abscess pointing in the middle of the posterior pillar of the soft palate. A small incision was made and about half an ounce of foul pus escaped. Pus continued to discharge and the swelling diminished. On Jan. 21st, 1900, four days after the abscess was incised, he complained of sudden severe pain in the throat. In a few minutes about six ounces of blood were lost. The hæmorrhage ceased on the application of tannic acid. Four hours later a hæmorrhage of about eight ounces occurred and was arrested by an astringent gargle. The urine contained much albumin, epithelial and pus cells, and granular casts. On Jan. 26th hæmorrhage to the extent of eight ounces occurred in the morning. In the afternoon the tonsillar and cervical tissues were distended and painful. Blood was still oozing from the opening in the posterior pillar and the abscess cavity was filled with clots. A large incision was made through the anterior surface of the soft palate and carried backwards until the abscess cavity was reached. After washing out the clots with hydrogen peroxide solution the ascending pharyngeal artery was seen at the outer posterior wall of the cavity. No ulceration could be discovered in its walls. The cavity was packed with iodoform gauze. The packing was changed daily for 10 days, the wound healed, and no further hæmorrhage occurred. Dr. Chappell has found in the literature of the subject reports of 10 cases of which only two terminated in recovery. The first case was reported in 1825 by Dr. Samuel Walker. There was double tonsillar abscess. The left abscess opened spontaneously. There was a swelling in front of the thyroid cartilage which on being opened was found to communicate with the right tonsillar abscess. Two days later the patient died from great hæmorrhage, the blood gushing from the mouth and nose. The second case was reported by Dr. Thomas Watson in 1828. Two days after a tonsillar abscess had been opened 12 or 14 ounces of blood suddenly gushed from the throat and nose. The hæmorrhage recurred on the same day and on the following days. Two weeks later bleeding took place after eating, and while preparations were being made to tie the carotid artery the patient died from suffocation. The necropsy revealed the trachea and bronchi full of blood and a large erosion of the lingual artery. In almost all the cases the abscess opened spontaneously and probably an early incision would have prevented the extensive ulceration which implicated a large vessel. Dr. Chappell recommends immediate ligature of the carotid artery on the occurrence of the first hæmorrhage or, as proved successful in his case, a free incision through the anterior wall of the soft palate and firm packing of the abscess cavity with gauze.

---

[1] THE LANCET, Feb. 16th, 1901, p. 495.

THE annual dinner of the West London Medico-Chirurgical Society will be held at Frascati's Restaurant, Oxford-street, W., on Wednesday evening, May 8th, at 7 for 7.30 P.M. Communications should be addressed to Dr. G. P. Shuter, Oaklands, Chiswick-lane, W.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on April 3rd states that for the week ending March 30th 60 new cases of plague were admitted, of which 18 occurred in Europeans and 29 among the coloured population. The deaths numbered 22, of which six were Europeans. The total number of cases reported up to March 30th is 287 and the total number of deaths is 99. Among persons under naval or military control there have been 28 cases with three deaths. A Reuter's telegram, dated April 9th, says that five fresh cases had occurred that day.

THE annual dinner of the Royal Army Medical Corps will be held on Monday, June 17th, at 7.45 P.M., in the Whitehall Rooms of the Hôtel Métropole.

HIS MAJESTY THE KING has graciously consented to continue his patronage to the Charing Cross Hospital, and has also signified his intention to continue to be the patron of the Royal Infirmary, Newcastle upon-Tyne.

THE Cavendish Lecture of the West London Medico-Chirurgical Society will be delivered at the Hammersmith Town-hall on Friday, June 21st, by Sir Richard Douglas Powell who has chosen Acute Cardiac Failure as his subject.

QUEEN VICTORIA JUBILEE INSTITUTE FOR NURSES.—The annual meeting of the Cardiff branch of this society was held on April 1st, under the presidency of Canon Thompson. The report stated that 1214 cases were nursed during the year, compared with 1151 in 1899, while the number of visits made amounted to 32,635, against 32,486 in the previous year. The financial statement showed that the income amounted to £862 and the expenditure to £916.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 1037.)

VIII.

MR. BURDETT-COUTTS (page 17, "The Sick and Wounded in South Africa") says that he has never admitted that the defective medical arrangements rested solely on the transport, but rather on inherent faults of management, bad discipline, want of initiative, and a general spirit of *laisser faire*. The report (page 28) declares: "The military authorities had to decide, and did decide, what materials should be first sent up into Bloemfontein according to the pressure of military necessities, which were so great that it was found impossible to let the medical officers have a free hand in forwarding to Bloemfontein hospital equipment and necessaries. The chief of the staff was the ultimate authority on all matters relating to priority in connexion with the transit of materials along the greatly congested railway." Again: "Throughout the period of difficulty the officers of the Royal Army Medical Corps did their best to urge upon the military the necessities of their patients and the importance of providing for them." Further (at page 40) it is stated that to meet undoubted serious deficiencies in hospital equipment at Bloemfontein "considerable purchases were made in the town, and Surgeon-General Stevenson, in his evidence, states that he bought all that was available." Heavy hospital equipment could not be got up for some time owing to difficulties of transport (page 26 of the report). The provision of bedsteads, we may add, with a force over long lines of communication is incompatible with mobility. Stretchers must and do suffice admirably for field hospitals. It will be seen, therefore, that the Commissioners thoroughly recognise that the medical service were placed at enormous disadvantages at Bloemfontein owing to difficulties of transport for which they had no responsibility.

With regard to the alleged delays in removing patients to hospital from the railway stations the Commissioners admit that delays did occasionally occur. With reference to an instance, however, which was described by Mr. Burdett-Coutts and Mr. Murray Guthrie as having taken place at Bloemfontein the report alleges in explanation that it was due to the accidental separation of a truck. Still, as regards the general charge it is not denied that where wagon transport had to be used there were hardships. But the total number of deaths that occurred in the trains in transit up to September, 1900, only amounted to 14 out of over 22,000 men, in addition to 21 who died within two days of arrival. We may say that while the hospital train service was admirably organised and well carried out the ordinary train service left, in our opinion, a great deal to be desired. It seems absolutely necessary on such occasions to make provision for the supply of refreshment to troops, not only at the various railway stations *en route*, but in the trains themselves. The supply should consist of fluid nourishment and the means of heating it; and similar provision should be made on field service generally at the various rest depôts wherever these exist along a line of march. Whilst upon this subject we may note that in a general way a medical officer charged with the administration of any big hospital in time of war requires to combine the qualities which make a successful manager of an hotel with those requisite in a medical chief of a hospital. There should always be ample supplies of hot fluid foods ready for administration to batches of sick and wounded whilst they are being told off to their wards and their names are being taken.

Those of our readers who have either read the whole or our summary of the Commissioners' report will have gathered that the time of the march from Bloemfontein to Pretoria and the stay in the capital itself involved much stress and strain, and implied a good deal of discomfort and misery to the sick and wounded. Nor can it be denied that there were more or less lack of equipment, deficiency of hospital necessaries and appliances, and, in some cases, defective discipline and disorder. But the fact is that the size and work of the army had become enormously augmented, and there was a great rush on all departments. The army had been out-marching its supplies and in every direction there was evidence of much shortcoming and undermanning A race was going on between demand and supply, in which the former was always outstripping the latter As a general rule, it is for obvious reasons advisable to have only one spending department for an army in the field, if only to avoid different branches of the army competing against one another in the *market to their own mutual disadvantage and to the enrichment* of the producer or seller But it is, of course, quite right that medical officers should be empowered to purchase from any local markets anything that may be needed to meet exceptional or emergent occasions, and they had this power, which they possibly did not sufficiently exercise, during the campaign in South Africa We need not go far, however, to seek the reason of this they and all concerned were too overburdened with work in attending to their hospitals and patients to have either the strength or the time to do aught else The fact is, that altogether too much labour and responsibility are imposed and concentrated on the medical service in time of war. If all is to go well with that service at such times it must have control over everything appertaining to its functions and the hospital and other requirements of the sick and wounded Wherever it has had to depend upon other departments for its supplies experience has shown that these supplies are not forthcoming at the time, or if so that they are not of the nature and amount required, and *consequently failure is the result* But the *possession of* authority and control need not necessarily be attended with increased personal labour on the part of those exercising it What would seem to be wanted is an executive department subordinate to, and under the orders of, the Royal Army Medical Corps which, without interfering with the power and responsibility which should rightly belong to that corps, should nevertheless relieve it of all purely military and *quasi* military duties, the charge of transport animals, and the making of purchases, for example The calls upon executive medical officers under the requirements of the present age in respect of their hospital and purely professional duties are very important The calls upon medical officers of administrative rank to see that the work of their subordinates is properly done and to organise, to superintend and to administer the medical arrangements generally for the force under their immediate medical charge are no less urgent It is advisable to relieve both classes of extra professional work as much as possible The way of doing this will be more fitly considered hereafter, meanwhile we may suggest that a portion of the Army Service Corps under its own officers might be told off in war for the exclusive use of the medical service and for the sole purpose of executing its behests

Want of enterprise has been alleged against the medical officers in not taking over and utilising more permanent buildings in captured towns for the use of the sick and wounded than was done Setting aside the difficulties of furnishing the requisite hospital establishments and equipment required for the purpose, there is room for honest difference of opinion in this matter It is astonishing how few public or private buildings are suitably constructed for hospitals in the way of cubic space, ventilation, and sanitary and cooking arrangements They may possibly afford better protection and more personal comfort to their occupants for the time being than can be obtained in shelters of a less permanent character, such as huts, tents, and marquees; but such additional protection and comfort are too often obtained at the expense of the sick and wounded in other respects The experience of all past wars and the lessons of sanitary science point in this direction Aseptic surgery, when it can be at all properly carried out, has proved most effective in war hospitals, but it is relatively inoperative where defective ventilation and overcrowding are present We have seen but few buildings, other than hospitals proper, which we should prefer to less permanent structures for the occupation of patients whilst under treatment for any serious wound or sickness

We may here make a few remarks on the way in which the military and civil surgeons worked together A few cases of friction, alluded to in the report occurred between the two classes in certain hospitals and we have heard of others, but as a rule the relations between them were harmonious and good and the civil surgeons employed in the campaign have, as a body, done their duty extremely well Civil surgeons labour under many disadvantages in a campaign They are new to the work and they know nothing, of course, of the routine and regulations of army life in the field Many things must naturally seem not only strange but strangely complicated, unnecessary, and irksome to them Moreover soldiers are no respecters of persons but respecters only of uniform, and if the civil surgeon wears no uniform soldiers have nothing to guide them "Tommy's" whole training leads him to look to and to regard the uniform and not its wearer as the outward and visible *sign of that commissioned rank which he is to respect* Soldiers are nevertheless keen observers and shrewd judges of character and professional merit, and any civil surgeon with the manner and bearing of a gentleman who is earnest and straightforward in the discharge of his duties will secure their confidence and respect even if he have no uniform It is usually, in our experience, the man who thinks more of himself and of his importance than of the interests of his soldier patients who fails to do so

What we have understood to be the feeling of army medical officers in regard to the employment of civil surgeons in war may be represented somewhat as follows As regards consultants of acknowledged repute, and drawn from the staffs of large hospitals their presence is always most welcome, not only because of the great professional value of their advice and aid alike to the medical staff and to their patients, but because they constitute a special jury of experts upon whose judgment the public may rely They can appreciate the difficulties and the success of the work that is being done by the medical service in the field Setting aside the case of consultants, where friction arises between the military element and the civil element faults will be found on both sides Men of the right stamp and character cannot always be secured for either class The military surgeon, for one thing, finds his labours increased rather than otherwise, perhaps, during the time that his civil *confrere* is acquiring some practical knowledge of the army regulations and system There is besides some room for the existence of a feeling, which is very natural under the circumstances, that any competition which may ensue between them is an unfair one to the regular army surgeon who has to work with the materials, and be bound by the system, provided by the Government Take the case of the army The regulars are to volunteers as professionals are to amateurs, however good the latter may confessedly be The hard work falls as a simple matter of duty to the lot of the former, they are expected, as disciplined troops, to exhibit superior powers of fighting and resistance and to sustain very serious losses rather than yield or fail in their attempts—qualities which they have certainly exhibited, as a rule, in this campaign But the military virtues of regular troops, like the contents of a lengthy and formal document, are too often "taken as read The big bold headlines in the daily papers are not usually for them and if one of the many heroic and distinguished regiments of the service were to return home to-morrow it would not be accorded the welcome which was given to the *C I V's* The officers of the Royal Army Medical Corps cannot, we imagine, help feeling that they, like the rest of the regular army, may do their best under the most trying circumstances without receiving any special meed of praise, while if there should be any shortcomings it would be they and not the trying circumstances that would reap the *discredit*

We have already *referred to some of the defects* and shortcomings of the train service The Commissioners at page 55 of their report allude to the many complaints and cases of *hardship* that arose in connexion with the conveyance *of* patients to and from fixed hospitals We may remark here that the Indian bearer service transport of the wounded *from* the battle field and properly fitted hospital trains are admirable systems of land transport, and water transport, always preferable, is not always available Where railway trucks are used they must be fitted with some sort of protection from the sun and with sanitary appliances in the shape of buckets or with openings in their floors leading into moveable metal tanks provided with chloride of lime or other disinfectant

The complaints about the hospitals on the lines of communication chiefly concern Sterkstroom and Norval's Pont As regards the former they partly refer to an alleged want of *attention and skill* and lack of consideration for patients shown by some of the staff of a field hospital attached to the camp of the Third Division The Commissioners say "Without endorsing to the full the complaints against the hospital, still, after making allowance for the fact that it was only a field hospital, we are satisfied that its management and condition were not satisfactory." With respect to Norval's Pont the Commissioners state that a number of the complaints appear to them to be substantial (*vide* pages 56 and 57 of the report). As everyone knows, some of the base hospitals at Cape Town have been subjected to much adverse criticism. Speaking generally, the Commissioners report very favourably of the condition of these hospitals and in support of that view quote the strong opinion of Colonel Cooper, the staff commander at the base, to the same effect.

At the conclusion of Part IV. of the report the Commissioners make a number of suggestions and recommendations of various kinds which as soon as the war is ended they consider should be decided upon by a departmental or other committee of experts. Among these are the following:—The staff of the Royal Army Medical Corps should be permanently enlarged and due provision made for its further necessary and speedy enlargement in times of great wars; inducements should be offered to insure a continuous supply to the corps of sufficient men of good professional attainments and those who have joined should be kept thoroughly acquainted with the general progress made in professional subjects and at a high professional standard of efficiency; increased and better provision should be made for scientific study and for promotion by merit; and there should be more nurses for fixed hospitals. The Commissioners also express the opinion that the committee which they think should be appointed might usefully consider whether the Royal Army Medical Corps should not have exclusive possession and control over all necessaries for the sick and wounded. They further recommend that strict inquiry should be made in the military hospitals now in South Africa, and proper steps be taken in order to stamp out, where it exists, pilfering by orderlies of the stimulants, comforts, or property of patients and the receipt of bribes by orderlies from patients. Several other points are likewise referred to on which we need not touch now. Speaking generally we quite concur with their suggestions and recommendations. Some of them are perhaps more easily made than carried out, such as the enlargement and increase of popularity of the Royal Army Medical Corps and the provision of a really efficient medical service adequate to the special needs and worthy of the position of a large empire like that of the British empire. As regards the Royal Army Medical Corps we know that it was thought that, when not only military rank but military titles were accorded to its officers, there would be no lack of medical candidates for the army. Such, however, is far from having been the case. Whilst agreeing generally, as we have said, with the suggestions and recommendations of the Commissioners, we think that the time has come for attempting to devise some larger and more comprehensive scheme than that which they have foreshadowed.

ASYLUM DYSENTERY.[1]

IT has become almost the custom to look upon dysentery as a tropical disease. Yet it is known that a disease which is identical in its clinical and pathological aspects with dysentery occurs more or less throughout Europe, and in past ages well-characterised epidemics of a wholesale kind have raged from time to time in temperate climates. Sometimes these have been limited to institutions, as was a well-known outbreak at the Millbank Penitentiary, and sometimes the disease has occurred with no such local associations. The word "dysentery" has also been employed to designate the disease which is recognised to occur in the lunatic asylums of this country and which is characterised anatomically by inflammatory lesions of the large intestine—colitis. The report issued on this subject by Dr. Mott and Dr. Durham will be found most comprehensive and complete. In an introduction the authors draw attention to the synonyms which have been employed to designate this condition and state their reasons for adhering to the term "dysentery." There certainly seems to be much scope for enlargement of our knowledge concerning the nature, causation, and distribution of dysentery in the tropical zone; but, as Dr. Mott and Dr. Durham point out, so far as the clinical and pathological accounts go there does not appear to be any essential difference between the dysentery of the warmer and that of the cooler climates, though on the whole the type of disease in the tropics may be more severe owing to the condition of the subject, the likelihood of complication with malaria, and the supervention of secondary infections and complications. The authors of the report, therefore, have acted wisely in retaining the term "dysentery" as applied to the disease the outbreaks of which they investigated, and we agree with them that until the exact nature is known of the essential cause in different countries medical men are not in a position to dogmatise as to what is and what is not properly called "dysentery." But it seems probable that such distinctive and similar lesions of the colon as are found in this country and in the tropics must be determined either by identical or by very closely allied agents. It is hardly credible that the same disease should be caused by amœbæ in one place, by a micrococcus in another, and by a variety of colon-like bacilli in others. In conducting their inquiry Dr. Mott and Dr. Durham necessarily had to rely much on the coöperation of the officers and staffs of the asylums, and they express their appreciation of the manner in which they were assisted. The main brunt of the attacks fell upon Hanwell, Colney Hatch, and Claybury. The authors had to rely upon a system of notification which they instituted. Much valuable information has thus been acquired, although they admit that the time during which the system has been in force is far too short for its result to become obvious. But future workers in this field of observation will reap the advantage.

A good account is given of the clinical and anatomical aspects of dysentery as seen in the asylums, and the diagnosis is carefully discussed. Considerable difficulty is often experienced in coming to a conclusion as to the nature of the complaint during life. In many cases the signs are not well marked. Beyond certain abnormal characters of the stools it is difficult to distinguish dysentery from simple diarrhœa. There are no sufficiently definite febrile periods or characteristic conditions of the tongue, skin, &c., and owing to the class of patient questions as to the existence of abdominal pain and the like cannot be put with any useful result. The mainstay of diagnosis consists, in short, in the observation of blood and slime in the stool, but there is no constancy in the composition of the fæcal material. The remarks on the etiology of the disease are most interesting. The authors arrive at the conclusion that it is possible that dysentery may be conveyed by means of the air, but they were unable to elicit any positive evidence that this does occur. Again, so far as the evidence obtained goes, it appears to exonerate the water-supply as the means of spread of dysentery, although this statement is open to certain reservations which are explained in the report. There was likewise no evidence that suggested the implication of the milk-supply. With regard to the water-supply also, if such a common source were at the root of the evil a far more extensive explosion of the disease would have been probable. The section of the report headed "Defective Sanitary Arrangements" affords interesting reading. There are evidently several matters deserving the attention of the authorities, although the outbreaks of dysentery could not be directly assigned to such defects. At Claybury there is an irrigation overflow, by means of which vegetable produce, such as salad and celery (both are eaten in an uncooked condition), are irrigated with raw and unscreened, untreated sewage. An examination of the effluent at a time when it had just been poured over a bed of lettuces showed not only that every cubic centimetre contained more than 1,500,000 bacteria, but abundant unaltered fæces were also present, suggesting that most of the bacteria were of fæcal origin. This amateur sewage treatment on asylum premises is unhesitatingly condemned by the authors of this report.

Another point that rightly receives censure is "imperfectly-regulated personal cleanliness." So far as the authors could ascertain, the rules in all the asylums lay down that there should be washing on rising every morning and a weekly bath when the condition of the patients admits. After the morning wash no further ablutions are compulsory until the following morning. Further, in some cases the lavatories are locked up after the morning ablutions until the next day, so that ordinary cleanliness would seem to be a matter of difficulty. A marked example of the possible danger of such a custom is instanced. In a ward where it had been

---

admitted that patients might have to assist in dealing with a certain diarrhœa case the ward lavatory was locked and the assistants would then have to go to the slop-sink to wash their hands, and whilst Dr. Mott and Dr. Durham were in the ward the excrement of
posed of down the same
of severe censure. It is
the attendants are much more careful. The wards of the

the purpose they are not available, seeing that they are filled up with ordinary chronic lunatics.

A somewhat grave indictment is found under the heading "On the Occurrence of Dysentery in the Asylums in Previous Years" No satisfactory records have been kept of the various outbreaks of dysentery that have occurred, and apparently but little effort has been made to check its spread. For instance, in the Claybury Asylum a severe outbreak of dysentery occurred in 1896, yet the disease has continued in the asylum ever since without any special attempt being made to take precautions to stamp it out, nor has any systematic record been kept as to the extent to which it has occurred. These matters demand immediate action on the part of the authorities who are responsible for the management of the asylums, and they will do well to give heed to the recommendations laid down in the report now under consideration. Dr. Mott and Dr. Durham offer certain suggestions which, if carried out, would do much towards stamping out the disease and improving the health *of the inmates of the asylums mentioned in the report.*

The authors may be congratulated on the results of their labours. In addition to the actual report data are given of the various visits made to the asylums, and of the conditions which existed in each as to arrangement of wards, lavatories, &c., and "tabulations of cases of dysentery and diarrhœa reported," are furnished. The whole volume is full of interest and we trust that the result of its publication will be a better knowledge of the nature of the disease and greater precautions against its spread. The London County Council have never shown themselves more alive to their great responsibilities than when they appointed an official pathologist to help them in their asylum work, and their public spirit in printing this report should certainly be rewarded by an improved condition of the health of the lunatics under their charge.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary meeting of the Comitia was held on Monday, April 1st, Sir WILLIAM SELBY CHURCH, the President, being in the chair.

The PRESIDENT read the gracious reply from His Majesty the King to the loyal address of the College which has already been published in our columns.

The PRESIDENT then delivered the annual address in which he reviewed the work accomplished by the College during the preceding year. The various communications that had been received from the Government, the royal distinctions that had been conferred on certain Fellows of the College, and the medals and prizes which had been awarded were duly referred to, as well as were numerous other matters which had from time to time engaged the attention of the College. Especial reference was made to the new conditions under which the University of London now exists The President then read brief notices of the Fellows of the College who had died during the past year—namely, Sir William Overend Priestley, Dr. Nicholas Tyacke, Dr. Daniel John Leech, Sir Henry Wentworth Acland, Dr. Dennis Embleton, Dr. John Cockle, and Dr John Baptiste Potter.

Dr. PAVY proposed and the Second Censor (Dr C. T WILLIAMS) seconded a vote of thanks to the President for his address, including a request that it should be published. This was carried The PRESIDENT having thanked the College vacated the chair. The Registrar (Dr. E LIVEING) having read the by-laws relating to the occasion, the election of President took place. The result was declared to be as follows: Sir W. S. Church, 94 votes; Sir W. Broadbent, three. Five voting papers were blank.

Sir William Selby Church was then declared to have been elected. The charge was delivered by the Senior Censor (Dr. W. Cayley) and the President pledged his faith to the
ain electing him,
th were nominated by

lasgow.
received. From the
ns of England reporting certain proceedings of the Council on Feb. 7th and March 14th last. From the General Medical Council announcing the expiration, on May 14th, 1901, of the appointment of Sir Dyce Duckworth as representative of the College in that Council. A letter was also read from Sir Dyce Duckworth resigning his position as that representative. The SECOND CENSOR proposed, and Dr PYE SMITH seconded, a vote of thanks to Sir Dyce Duckworth for his services. This was carried with acclamation.

A report was received and adopted from the Committee of Management, dated Feb 25th, 1901. Amongst other matters the report set forth the new regulations of the General Medical Council for Diplomas in Public Health, and recommended that the Croydon Borough Hospital should be added to the list of fever hospitals recognised by the College.

Certain alterations in the by-laws were also announced as follows:—

The REGISTRAR moved that By-law CXXXVI. be amended and re enacted for the second time as follows, to render it conformable to the regulations of the Conjoint Board, the alteration consisting in the addition of the words printed in italics.—

This was carried.

The REGISTRAR moved that By-law CXLV. be amended by the omission of the words printed in italics in the copy below to make it conformable to the regulations of the Conjoint Board and re enacted for the first time.

BY LAW CXLV.

Any Member of a Scottish or Irish University *where it is required*
[illegible]
shall comprise the subjects of the First and Second Examinations of the College, and who shall have completed the curriculum of medical study required by the Regulations of his University shall, two years after having passed all the other required Examinations, be eligible, on payment of the requisite Fees, for admission to the Third or Final Examination

The PRESIDENT then dissolved the Comitia

ASYLUM REPORTS.

Hereford County and City Asylum, Burghill (Annual Report for 1899).—The average number of patients resident during the year was 367 and comprised 171 males and 196 females. The admissions during the year consisted of 75 patients—viz, 41 males and 34 females. Fifty of the patients admitted were first admissions, the rest being re admissions Mr. C S. Morrison, the medical superintendent, states in his report that of the admissions 57 per cent of males and 54 per cent of females were over 60 years of age, "an age at which the climacteric in the life of the individual is attained and a period when slight causes operating to disturb the state of health render the return to health precarious and difficult of attainment." It is pointed out that many cases of senile mental decay certified as insane and brought to the asylum would, with a little care and supervision, be more suitable for the workhouse, and it is suggested that it would be well if some provision were made in the Poor-law by which such cases should be assigned to the workhouse instead of placing them "under the same expensive hospital conditions in which the acute and recent cases are properly placed" Mr. Morrison suggests a procedure to meet these ends—viz., that the certificate of the medical superintendent of the asylum to the effect "that the mental alienation (of a patient admitted) does not come within the meaning and definition of the Lunacy Act" might be made sufficient to secure the removal of the person to the workhouse. Any tendency on the part of the asylum superintendents to transfer too readily a case from the care of an *asylum would be adequately met by the provision that* the certificate was to be given in consultation with a duly appointed local medical practitioner unassociated with either institution, asylum or workhouse. "This is a subject worthy of serious consideration by the State, in view of the ever-increasing burdens placed on the tax- and rate-payers." At present asylums are converted into "dumping grounds for all mental defectives, whether idiots, imbeciles, epileptics, senile dements, or cases of actual insanity, and the special needs of each class are in consequence neglected or only partially met." Mr. Morrison points out that in some patients there exist "germs of a diseased egoism in such a type which readily assimilates the cult of destructive anarchism," and that such patients may, under suitable conditions, be propagators of a progeny dangerous and unprofitable to the community. During the year 26 patients were discharged as recovered, or 7 per cent. of the average number resident. The deaths during the year amounted to 34—viz., 21 males and 13 females, or 9·2 per cent. of the average number resident. Among the deaths two were due to chronic renal disease, four to epilepsy, four to phthisis, five to general paralysis, and 15 to atrophy of the brain. Two inquests were held during the year and the verdict in each case was that of "Death from natural causes." "A higher recovery-rate and an increased death-rate, with what may be termed a normal average admission-rate, is accountable for the net decrease in the numbers shown in the statistics of the year." The asylum was visited by two severe epidemics of influenza, with the result that a considerable number both of the patients and of the staff was attacked. The absence of an isolation block for infectious cases is severely felt, patients affected by the influenza being scattered in wards throughout the building and thus directly infecting others and causing its dissemination. The same difficulty was experienced in treating an outbreak of facial erysipelas among the patients. Active measures were adopted to stamp out tuberculosis among the cows on the farm and they were attended with complete success.

Dundee Royal Asylum (Annual Report for 1899).—The average number of patients resident during the year amounted to 411 and comprised 172 males and 239 females. During the year 105 cases were admitted—viz., 49 males and 56 females. Of these 22—viz., 10 males and 12 females—were not first admissions. Dr. James Rorie, the medical superintendent, states in his report that the number of private patients continues steadily to increase. The number of cases discharged as recovered during the year amounted to 46—viz., 18 males and 28 females, or 11·1 per cent. of the average number resident. The deaths during the year amounted to 41—viz., 16 males and 25 females, or 9·9 per cent. as calculated on the same basis. "The physical condition of the patients on admission has been very similar to that of former years. The forms of mental illness of those admitted do not show any departure from the records of previous years worthy of notice." Among the causes of insanity in the *persons admitted* there were previous attacks in 27 cases, alcoholic intemperance in 18 cases, mental anxiety, worry, and overwork in 16 cases, old age in 14 cases, and heredity in 14 cases; 13 cases were the outcome of frail physical health. Of the deaths during the year five were due to phthisis, 10 to senile decay, and 10 to general paralysis of the insane. The building for private patients is nearly completed, and when finished will not only supply a want that has been *much felt in the past* but will put the institution in a position "to meet any demand that may be made upon it for years to come for the admission of patients of whatever class or social position." To make the building complete a separate chapel has still to be erected, the religious services at present being conducted in the largest day-room on the female side of the house. This can, however, only accommodate about 180 persons, while fully two-thirds of the patients could be present were a proper building provided. The committee of management *recently* desired to raise slightly the charge of maintenance per head for pauper patients and submitted proposals accordingly to the General Lunacy Board who intimated their decision that 12*s.* 6*d.* per week should be the rate chargeable per head for pauper patients. The Lunacy Commissioners in their report speak favourably of the management of the institution and of the general comfort and appearance of the patients.

Warwick County Lunatic Asylum (Annual Report for 1899).—The average number of patients resident during the year was 964 and comprised 396 males and 568 females. During the year 226 patients were admitted and of these 181 were first admissions, comprising 89 males and 92 females. Dr. Alfred Miller, the medical superintendent, states in his report that 87 of the patients (all females) were chargeable to the County of London. The number of admissions was about the same as in the previous year, and included among them were the following cases: idiots 17, epileptics 10, general paralytics 9, and chronic maniacs *and dements 51. Three cases were found not insane on* admission, "one was an alcoholic vagrant, a type that often finds a temporary home in an asylum. A second presented some slight signs of mental aberration but not sufficient to justify detention. ...... The third in this category was a girl who might possibly be considered to belong to the type of moral insanity. She remained for some weeks under close observation. Finally, we came to the conclusion that we were not justified in detaining her as her actions and conduct seemed to be simply that of a cunning and crafty criminal." The patients discharged as recovered during the year amounted to 84, of which 44 were males and 40 females, or 21·5 per cent. on the average number resident. The deaths during the year amounted to 96, being 48 of each sex, or 24·2 per cent. of the average number resident. Of the deaths four were due to senile decay, six to epilepsy, 11 to cerebral apoplexy, 13 to cardio-valvular disease, 14 to general paralysis of the insane, 16 to pneumonia, and 17 to pulmonary phthisis. There were no deaths from violence during the year. Referring to the excessive death-rate from phthisis due to such conditions as overcrowding, deficiency of fat-forming foods, and the low vitality of chronic insane patients, Dr. Miller observes that "in former days we had (in this asylum) overcrowding to a great extent, we had a system of drainage of most defective character, and our ventilation system required a great deal to make it efficient." Notwithstanding improvements in drainage and ventilation an excessive mortality from phthisis still exists. Recently, therefore, provisions were urged and plans were submitted for an isolation block for phthisical patients designed to accommodate 24 patients, 12 of each sex, and the hope is expressed that the "necessary powers will soon be obtained from the county council to carry out the work." The desirability of a joint pathological laboratory for the midland counties is referred to and the hope is expressed that the new Lunacy Bill, which will allow for such a provision being undertaken by two or more joint counties, will soon become law. Owing to the need for the services of the reservists the staff on the male side was very much disorganised, 11 men having been called out. The farm continued to be in good condition, the supply of meat and vegetables being more plentiful than in former years. The Lunacy Commissioners in their report state that the case-books and medical records are properly kept and that the former are illustrated by good photographs.

BRISTOL EYE DISPENSARY.—The annual meeting of the subscribers to this institution was held on April 2nd under the presidency of Mr. P. J. Worsley. The medical report showed that 1776 patients had been treated, as compared with 1762 in the previous year. The financial statement was satisfactory. The committee regretted the death of the honorary treasurer, Dr. J. E. Prichard, who for the past 15 years had also assisted in the out-patient department of the dispensary.

VACCINATION PROSECUTIONS.—At the East Kerrier (Cornwall) Police-court on March 27th a tradesman was summoned for neglecting to have his child vaccinated. Defendant stated that his mother lived in a house adjoining his and the public vaccinator called there and did not make the offer to vaccinate the child to himself or to his wife. The case was dismissed. A farmer was also summoned for the same cause and said that he objected to vaccination as he had lost three children through it. The chairman remarked that the defendant must be under a great misapprehension in thinking that his children died owing to vaccination and made an order for the vaccination of the child.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Erdington Urban District.—Dr. Bostock Hill, in dealing with the question of isolation, refers to the fact that a large number of enteric fever patients were removed during 1900 from Birmingham and Aston to the workhouse infirmary. It appears that patients thus removed have been instrumental on more than one occasion in conveying enteric fever to other persons in the infirmary, and Dr. Hill suggests that it is very undesirable that enteric fever patients should be brought from outside the district into the workhouse. He observes that views as to the infectivity of enteric fever have undergone a considerable change within recent years, and there are many medical officers of health who condemn the practice of treating cases of this disease in the ordinary wards of a general hospital. Erdington would appear to possess no isolation hospital of its own, but the council has an arrangement with Aston for the isolation of scarlet fever and small-pox. Dr. Hill urges his district council to provide accommodation both for enteric fever and diphtheria.

Ormesby Urban District.—The medical officer of health of this district has done some good work during 1900 by inspecting the condition of the farms under his jurisdiction. The details of the inspection do not form pleasant reading and it is obvious that the administration of the local authority in this matter has been very slack. We are told that "for many years the same farms have been complained of, but almost nothing done to comply with notices served, or else the work has been commenced and afterwards allowed to drop altogether." In the detailed report we read of insufficient cubic space for the cows, of dung-heaps near bedroom windows, and of water-supplies unfit for domestic use. Both the farmhouses and the farmyards appear to be frequently in a deplorable condition and it is difficult to understand how anything approaching a pure milk-supply can proceed therefrom. We trust that the medical officer of health will be supported in his endeavour to obtain improvement.

Aldershot Urban District Council.—This district council have recently provided a laboratory for the analysis of water and for bacteriological diagnosis. As Dr. Thomas Dunlop, the medical officer of health, observes, this provision saves both expense and time, and the latter element especially is of vast importance in diphtheria, wherein the early treatment by antitoxin may just turn the balance between life and death. In the matter of the health of cows we are glad to see that the Aldershot cowkeepers appreciate the value of fresh air and that even during the winter months the cows are turned out for a certain time each day. The Aldershot District Council have provided some capital filter-beds, both primary and secondary, composed of clinkers of different sizes. The primary beds are apparently "contact" ones, while in the secondary beds the flow of sewage is continuous. We believe that the district council have taken much trouble in arriving at the method of sewage disposal best suited to their sewage, and it is therefore gratifying to learn that the method now in vogue has enabled the cost of chemicals, as used in chemical precipitation, to be saved and to be expended in the construction of new filter-beds.

Teignmouth Urban District.—Dr. F. C. H. Piggott reports that the attempt to introduce a scheme of voluntary notification of phthisis in Teignmouth has not met with much success although a fee of 2*s.* 6*d.* was offered by the district council. There were but two medical men in the district who undertook, *subject to the patient's consent*, to notify cases of phthisis. No notifications were, however, received. The registrar of deaths was also asked to inform the sanitary authority of every death registered from phthisis, but no information in this sense was received from the registrar. Dr. Piggott advises that a further effort be made to bring about a better state of local feeling on the subject. But the experience is of interest in relation to the general problem of notification. Teignmouth is still without the means of efficiently disinfecting infected clothing and bedding, and it is well that visitors to Teignmouth should be aware of this fact. Apparently the district council proposed to erect a disinfecting apparatus on the top of the sewage tank and the Local Government Board have, very naturally it seems to us, taken exception to the site. The surveyor reports that additional water is needed for the district and the council are said to be considering the question.

Greenock Urban District.—Dr. James Wallace in furnishing the figures for the mortality from phthisis and other tuberculous diseases in Greenock attributes the decrease which has taken place since 1875 to what he terms the "general sanitary operations" which have been operative since that date rather than to any of the measures proposed of late. By this latter expression we infer that Dr. Wallace is somewhat sceptical as to the value of notification, isolation, and spittoons, as also of the recent efforts to detect the tuberculous udder and to render the milk drawn therefrom unavailable for human consumption. Dr. Wallace places in the first rank of the necessary measures the endeavour to prevent the *predisposition* to the disease by means of the reduction of overcrowding and by rendering the houses of the poor more fit for human habitation. Certainly, whatever views may be held as regards the importance of predisposition, the steps suggested can hardly fail to have a considerable influence upon the reduction of the disease.

The Borough of St. Marylebone.—Mr. Wynter Blyth, in his report for February, expresses his opinion upon certain of the water regulations recently brought forward by the metropolitan water companies, and he does this upon the assumption that such regulations may be re-introduced at a future date. With the attempt to limit the capacity of the flushing cistern to two gallons he has no sympathy; he regards it as entirely wrong in principle and urges that if a water company is allowed to dictate the amount of water necessary for this purpose—an amount which varies with the type of closet—the next step may be to dictate the amount of water to be allowed for personal ablution. With respect to the proposed provision of sufficient storage accommodation Mr. Blyth estimates that in this district an expenditure of at least £20 per house would have been required, and he sees no sufficient hygienic advantage to be derived therefrom. He thinks that it would have been a wiser course on the part of the companies had they protected themselves against wilful waste by adopting the meter system.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6593 births and 4341 deaths were registered during the week ending April 6th. The annual rate of mortality in these towns, which had been 18 4 and 19 7 per 1000 in the two preceding weeks, declined again last week to 19 2. In London the death-rate was 17 6 per 1000, while it averaged 20 2 per 1000 in the 32 provincial towns. The lowest death-rates in these towns were 9 7 in Croydon, 11 8 in Birkenhead, 12 5 in Brighton, and 13 6 in West Ham; the highest rates were 24 3 in Manchester, 24 7 in Salford, 24 8 in Wolverhampton, and 27 7 in Liverpool. The 4341 deaths in these towns included 380 which were referred to the principal zymotic diseases, against 356 and 427 in the two preceding weeks; of these 109 resulted from whooping-cough, 105 from measles, 64 from diphtheria, 41 from diarrhœal diseases, 39 from scarlet fever, and 22 from "fever" (principally enteric). No death from any of these diseases occurred last week in Croydon, in Brighton, or in Norwich; in the other towns they caused the lowest death-rates in Plymouth and in Huddersfield, and the highest rates in Liverpool, Sheffield, Sunderland, and Gateshead. The greatest proportional mortality from measles was registered in Liverpool, Bolton, Sunderland, and Gateshead; from scarlet fever in Blackburn; from whooping-cough in Bristol, Swansea, Wolverhampton, Derby, Sunderland, and Gateshead; from "fever" in Halifax; and from diarrhœal diseases in Halifax. The 64 deaths from diphtheria included 21 in London, eight in Sheffield, four in Leicester, and four in Salford. No fatal case of small-pox was registered either in London or in any of the 32 large provincial towns; and no small-pox patients remained under treatment in any of the Metropolitan Asylums hospitals on Saturday, April 6th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1572, against numbers declining from 2535 to 1568 on the 13 preceding Saturdays; 180 new cases were admitted during the week, against 130, 151, and 167, in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 332 and 363 in the two preceding weeks, declined again last week to 360, and were 51 below the corrected average. The causes of 66, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Oldham, Leeds, Newcastle, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Halifax, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·1 and 21·6 per 1000 in the two preceding weeks, further rose to 24·1 during the week ending April 6th, and showed an excess of 4·9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·1 in Leith and 20 8 in Edinburgh to 26·7 in Greenock and 28·1 in Paisley. The 757 deaths in these towns included 57 which were referred to whooping-cough, 16 to measles, eight to diphtheria, eight to diarrhœa, six to "fever," five to small-pox, and two to scarlet fever. In all, 102 deaths resulted from these principal zymotic diseases, against 87 and 93 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·3 per 1000, which was 1 6 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had declined from 67 to 36 in the five preceding weeks, rose again last week to 57, of which 31 occurred in Glasgow, 13 in Edinburgh, and 10 in Dundee. The deaths from measles, which had been eight and 17 in the two preceding weeks, declined again to 16 last week, and included eight in Edinburgh, three in Leith, and two in Glasgow. The fatal cases of diphtheria, which had been seven and six in the two preceding weeks, rose again last week to eight, of which five were registered in Glasgow and three in Edinburgh. The deaths from diarrhœa, which had been 15 and 16 in the two preceding weeks, declined again to eight last week and included five in Glasgow. The fatal cases of "fever," which had been six and four in the two preceding weeks, rose again last week to six, of which four occurred in Glasgow and two in Greenock. The deaths from small-pox, which had been 24, 11, and 10 in the three preceding weeks, further declined to five last week, and were all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 126 and 127 in the two preceding weeks, further rose last week to 150, but were slightly below the number in the corresponding period of last year. The causes of 44, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 36 6 and 34·0 per 1000 in the two preceding weeks, further declined to 31·9 during the week ending April 6th. During the past four weeks the death-rate in the city has averaged 34·3 per 1000, the rates during the same period being 17·9 in London and 22·7 in Edinburgh. The 212 deaths of persons belonging to Dublin registered during the week under notice were 14 less than the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 15 and 14 in the two preceding weeks; of these, 5 resulted from whooping cough, four from "fever," two from diphtheria, and one from diarrhœa. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rates during the same period being 1·6 in London and 4·4 in Edinburgh. The fatal cases of whooping-cough, which had been 11·7 and 0 in the three preceding weeks, rose again to five last week. The deaths referred to different forms of "fever," which had been two and one in the two preceding weeks, rose again last week to four. The 212 deaths in Dublin last week included 29 of children under one year of age and 58 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons corresponded with the respective numbers in the preceding week. No inquest case was registered, but four deaths from violence occurred; and 79, or more than one-third, of the deaths were recorded in public institutions. The causes of 7, or more than 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon Charles James Seddon Kelsall has been placed on the retired list. Surgeon Edward Butler Pickthorn has been promoted to the rank of Staff Surgeon.

The following appointments are notified: — Fleet Surgeons: I. H. Anderson to the *Duke of Wellington*, for Portsmouth Dockyard; W. R. White, R M.L.I., Portsmouth; R. Bentham to the *President;* H. A. W. Richardson to the *Magnificent;* and R. D. White to the *Achilles*, for Malta Dockyard. Staff Surgeons: B. O. E. F. Gunn to the *Hannibal;* W. E. Home to the *Galatea;* James Bradley to the *Pyramus;* and J. R. McDonnell to the *Achilles*, for Malta Dockyard. Surgeons: M. H. Knapp to the *St. Vincent;* J. H. Pead to the *Wildfire*, temporary; J. T. M. McDougall to the *Duke of Wellington;* J. N. Robertson to the *Research;* L. Kilroy to the *Achilles*, and S. H. Facey to the *Achilles*, for Malta Dockyard.

ROYAL ARMY MEDICAL CORPS.

Major R. Caldwell assumes medical charge of troops, Station Hospital, &c., Maryhill, Glasgow. Lieutenant-Colonel D. L. Irvine has arrived in the Eastern District for duty, and assumes temporary medical charge at Bedford during the absence on sick list of Lieutenant-Colonel Poynder, r.p.

The undermentioned Civil Surgeon, serving in South Africa, to be Lieutenant: James Herbert Roche Winder.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Robert Sinclair Smith to be Surgeon-Major.

YEOMANRY CAVALRY.

Royal 1st Devon: Murray Babington Stuart to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Cornwall (Duke of Cornwall's) (Western Division Royal Garrison Artillery): Surgeon-Major W. K. Bullmore retires with permission to retain his rank and to wear the uniform of the corps on his retirement. 1st West Riding of Yorkshire (Western Division, Royal Garrison Artillery): Percy James Sandys Bird to be Surgeon-Lieutenant. *Rifle:* 2nd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant D. Smart to be Surgeon-Captain. 3rd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Alexander Waugh to be Surgeon-Lieutenant. 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Surgeon-Captain G. Bell Todd to be Surgeon-Major. 1st Dumbartonshire: Brigade-Surgeon-Lieutenant-Colonel P. F. Robertson resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement, vacating at the same time the appointment of Senior Medical Officer to the Clyde Volunteer Infantry Brigade.

SOUTH AFRICAN WAR NOTES.

Major Wyatt is reported to be progressing favourably (Bloemfontein, April 3rd). Captain H. G. Martin, R.A.M.C., Captain F. McDowell, R.A.M.C., and Lieutenant Black, R.A.M.C., have been discharged from hospital to duty.

MALARIA AND MOSQUITOES IN GERMAN WEST AFRICA.

In the *Archives de Médecine et de Pharmacie Militaires* for March Dr. A. Billet briefly reviews the papers entitled "Malaria and Mosquitoes on the West Coast of Africa" which were recently published by Dr. Ziemann of the German navy as the result of his personal investigation in the Cameroon and Togo districts during a period of 16 months from March, 1899, to July, 1900. The conclusions drawn by the reviewer, seven in number, are to the following effect: 1. The mortality of the regions in question is very high, being at the rate of 9·8 per cent. for a strength of about 186 Europeans. The greater part of it is due to malaria which presents itself chiefly under the form known as tropical fever. 2. In persons who have not as yet undergone treatment by quinine this disease assumes the malignant tertian type, being characterised by paroxysms of 24, 48, and even of 72, hours' duration, broken by remissions when the temperature falls about 2° or 2·5° F. This kind of fever, accordingly, fully deserves the name of remittent, irregular, or continued fever, in spite of the assertion of R. Koch who denies the existence of such beneath the tropics. In relapses the disease usually assumes the form of simple tertian. The hæmatozoon is constant. It presents itself under the annular form and may contain [illegible]. Tropical fever ought to be pla[illegible]e æstivo-autumnal fever of the [illegible]ing to Koch, being identical. 4. The alleged immunity of the negro race to malaria does not in reality exist. The truth is that the blacks exhibit all the stigmata of palustral infection from their earliest infancy, splenic enlargement being one of the most common. The malarial immunity enjoyed by coloured races is merely acquired and relative. In the Cameroon district inoculation with infected blood was practised, with their own consent, on a number of negroes, the result in 71 4 per cent. of the cases being positive. 5. From a therapeutic point of view quinine remains the sovereign medicament *par excellence*, being far superior to all others, inclusive of phenocol and methylene blue. Quinine should be given during intermissions, five or six hours before the expected paroxysm. The maximum amount per diem, and also per dose, is two grammes. After the paroxysm is over the patient should take one gramme daily for three days. During the next three weeks he should take half a gramme every second day, and after that the same amount every fourth day. Half a gramme of quinine is also most suitable for prophylaxis, a procedure of which Dr. Ziemann is an ardent partisan. 6. With regard to the burning question of the transmission of malaria by mosquitoes it is well to remember that the honour of having been the first amongst German observers to demonstrate this transmission in an irrefutable manner is beyond controversy due to Dr. Ziemann. He found in the Cameroon and Togo districts four different species of anopheles of which about 30 per cent. contained the "coccidies" of malaria. Subsequently he followed up the evolution of the sexual forms of the human parasite in the stomachs of the mosquitoes and their definite transformation into these same coccidies. This evolution would seem to take place more slowly than in the Italian mosquitoes—that is, in between 10 and 16 days. There exists, moreover, in the Cameroons a species of black culex having its feet ringed with white which stings man very severely, and that not only by night but also during the daytime. It would seem that this species is equally capable with the anopheles of transmitting malaria The biological and distinctive characteristics of the culex and the anopheles are minutely described. The larvæ of the latter develop themselves exclusively in the pools of limpid water containing green algæ which border the paths, whereas those of the culex thrive in stagnant waters of every kind. 7. In a final section Dr. Ziemann examines the question whether man is the sole intermediary host of the malarial parasite, and takes the opportunity of recalling the circumstance that long before Dionisi made his observations in Italy he had found a parasite very closely resembling those described above in the blood of various kinds of bats on the West African coast. He has, likewise, met with very nearly similar organisms in sundry smaller members of the monkey family, as well as in a chimpanzee of the French Congo. It is, however, difficult to come to a conclusion regarding the identity of these organisms with the hæmatozoon of Laveran.

SOUTH AFRICAN WAR AFFAIRS.

As it was after the Burma war and so many other wars of this and other countries so it has proved with the Boers in South Africa. It has not followed that because their forces have been routed and their strongholds have been taken that fighting has thereupon ceased. There has succeeded a stage of desultory warfare of the guerilla and marauding type of a very trying kind, and this we seem still likely to have for some time yet in South Africa In a vast country where there are so few houses and buildings that 50 or more miles of veldt may be traversed without seeing any except at and around the railway stations, there is plenty of room for this sort of warfare and for occasional raids on small and comparatively weak posts and on the lines of railway. Still the latest news from Lord Kitchener about the systematic sweeping of the country and the repeated capture of horses, cattle, and ammunition and stores of all kinds and the success of General Plumer's expedition to Pietersburg, must sooner or later bring things to an end. There will still remain, however, the settlement of the country and the decision as to what is to be done hereafter with the large number of prisoners at St. Helena and Ceylon. There is very little medical news, nor are we likely to obtain any from the columns in active movement in various directions throughout the country. Enteric fever is still prevalent, but to nothing like the extent that it was. Although there has been much desultory fighting the number of casualties on either side has been small. The Boers, although they harass the British troops occasionally by attacks on a small scale, very rarely make any stand. The most important medical news is that connected with the plague which, according to the telegrams reporting its progress, appears to be getting a firmer foothold in Cape Town and its vicinity. As we go to press we hear rumours to the effect that De Wet's intellect has become affected and that Louis Botha is desirous to treat for peace.

VOLUNTEER MEDICAL ASSOCIATION AMBULANCE CHALLENGE SHIELD.

This challenge shield, of the value of 200 guineas, is offered for competition by the Volunteer Medical Association to encourage ambulance training in volunteer regiments and is held for one year by the regiment winning at the annual competition. The competition is open to stretcher squads composed of certificated regimental bearers belonging to any corps in the Volunteer or Yeomanry Forces and the Honourable Artillery Company (the Volunteer Medical Staff Corps and Volunteer Infantry Brigade Bearer Companies are excluded from the competition by the terms of the trust deed under which the shield is held, and non-commissioned officers above the rank of corporal are not eligible), and takes place at Wellington Barracks on June 1st. Particulars can be obtained from J. J de Zouche Marshall, Surgeon-Major, A.M R, 3rd Volunteer Battalion East Surrey Regiment.

H M S. "BRITANNIA."

The cadets returned to H M S. *Britannia* after a month's absence on April 1st. A number of alterations and improvements have been made at the suggestion of the medical board recently appointed by the Admiralty. Hammocks for 25 cadets have been slung aft, thus materially extending the amount of space in the sleeping decks for each cadet.

DEATHS IN THE SERVICES

Deputy Surgeon-General Andrew Fleming, I.M.S. (Bengal), on March 25th at Edinburgh, aged 79 years.

Correspondence.

"Audi alteram partem."

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr Archdall Reid, in his letter of April 6th to give point to his condemnation and satire of legislation against national intemperance, asks two questions. In the north we have a way of answering one question by asking another. He first asks for evidence in support of "M.D, B S. Lond.'s" statement that "habits of intemperance in either parent tend inevitably to produce conditions which act unfavourably upon the children and interfere with the healthy development of both mind and body." Does Dr. Reid believe (with all modern medical writers on these subjects) that gout, rheumatism, and the neuropathic diathesis are hereditary conditions? If he does believe this, on what evidence has he founded his belief?—on the consensus of educated medical observation or on the recorded figures of a series of individual family histories concerning, [illegible] such as would be sufficient to [illegible] but scientific statistician? A [illegible] Reid must well know that if all efforts to cure and prevent disease were arrested until the scientific statistician was fully satisfied by figures we should probably have to wait till the next century before anything was done. He must know that in medicine a strong consensus of skilled observers, a strong probability, and hypotheses that best explain the facts have all led to successful efforts for the treatment and prevention of disease. Dr. Reid can find for himself any number of recorded family histories in which alcoholism was the main element in individual and race degeneration. I maintain that the general consensus of medical observations strongly and almost unanimously agrees with "M.D., B.S. Lond.'s" conclusions. I believe the following quotation from Dr. John Macpherson's recent admirable work on "Mental Affections" will be homologated by 99 out of every 100 members of our profession: "From such facts as the foregoing, and many others of a similar nature which might be cited, we perceive that the influence of alcoholic excess in the parents induces in their descendants a debilitated constitution, disorders of nutrition, a low resistive power, a tendency to contract infectious diseases; in short, a general neurosis or diathesis out of which may spring one or other of the numerous affections of the nervous system which depend upon disordered nutrition."

Dr. Reid's second question takes the form of a challenge "to indicate a single instance in which prohibitory laws have not been followed by increased drunkenness as well as by a general degradation of the public morals." Few of us advocate "prohibitory" laws, but many of us do strongly urge on the State to increase the control and regulation of the excessive sale of alcoholic drinks. On these lines I take up Dr. Reid's challenge. In 1833 Norway had no excise or licensing laws and the consumption of spirits then amounted to 16 litres per head of the population, drunkenness being lamentably prevalent and increasing. The effects of this on the public health and morals were so bad that the Norwegian Government passed a stringent law controlling and regulating the distilling and sale of spirits. The good effects of this legislation were at once apparent, and in 1899 only 3·3 litres of spirits per head of the population were consumed. In short, Norway as a nation has been made sober, not by religious or moral suasion, but by legislation controlling and regulating the sale of spirits. The moral state and health of the people have been enormously improved. If Dr. Reid will pardon me, I would like, with much deference, to make two suggestions. Let him carefully study the facts about alcohol and alcoholic legislation to be found in Messrs. Rowntree and Sherwell's recent work. Let him also go into a low street in London, Glasgow, or Edinburgh when the public-houses are shutting on a Saturday night and thus study the price of possible alcoholic immunity that is to come 200 years hence in his fellow creatures who emerge from those houses, and let him then accompany a few of them to their homes, taking a look at their children to see the signs of degeneration, hereditary or otherwise. If modern preventive medicine had pursued a fatalistic inertia founded on letting the doctrine of the survival of the fittest take its natural course the death-rate of Great Britain would still have been about 25 per 1000 of the living. Surely the man who uses any theoretical doctrine—of alcoholic immunity or otherwise—as a spoke in the wheel of health reform or social amelioration incurs a tremendous responsibility and should be very sure of his ground.

I am, Sirs, yours faithfully,
T. S. Clouston.
Edinburgh, April 8th, 1901.

THE MEDICAL PROFESSION AND THE BUDGET.

To the Editors of The Lancet.

Sirs,—There is no doubt that the income-tax presses most heavily upon the professional classes, and of the professions to the greatest degree upon the members of the medical profession, because their lives and healths are the more precarious and exposed to the assaults of disease both by night and day. As it is well known that their expectation of life is the shortest of all the professions, consequently their productive period is also of the shortest. After a most costly education the medical man finds that his working expenses are greater than that of any other profession, that his bad debts are more numerous, and that the calls upon his charity are such that the profession to which he belongs probably contributes in value three-fourths of the vast medical charities of the kingdom.

The medical and surgical services gratuitously given to the sick poor and to those who consider themselves poor represent a pecuniary value of some millions of money—a grant in aid of the sick poor, contributed to alone by the medical profession, and by so much relieves the rates, both county and parochial, because, if it were not for medical charity this medical and surgical aid would have to be provided by the public and paid for by taxation. An argument, as shallow as it is exasperating, is always trotted out by hospital committees and lay managing secretaries on this point to the effect that the experience gained by the medical staff in working for nothing more than squares the bargain. They do not see that the same argument applies to all professions. A new judge or barrister, or Prime Minister or bishop, or managing director, in the course of the practice of their calling, obtain valuable experience—they get paid for it all the same. They are not told, as we are, that the experience and reputation attached to holding a prominent public appointment is in itself a sufficient reward and pecuniary discharge in full for value received. The public fail to see, and we are too backward in proclaiming, that experience *per se* gained in giving gratuitous medical service has no value that it would not equally possess if those services were adequately remunerated. It is necessary to emphasise this point in view of the many hospital management controversies now raging. It can be shown, therefore, that the relation of the medical profession to the public is in this way different to that of any other profession or calling, and consequently we can claim special treatment and leniency in the matter of taxation. Instead of leniency, as a body, we are exploited and practically scalped, and skinned by successive Chancellors of the Exchequer. At one of the recent Budgets one of the Chancellors actually chuckled with delight at the amount of income-tax that had been squeezed out of the medical profession and our profession was so feebly represented in the House that there was no one sufficiently instructed or articulate to explain that the exigencies of their calling prevented medical men from appealing against excessive assessment or agitating against the unequal incidence of direct and indirect taxation which pressed so heavily upon their burdened shoulders.

To condescend to particulars I would suggest: (1) that the medical man's house should be rated and assessed as a house of business; and (2) that the payments to sick and benevolent societies should rank with life assurance premiums and be deducted from income for taxation purposes.

Provision in case of sickness or poverty is as worthy of national encouragement as providing for early death—indeed, they are often linked together in one sad chain of misfortune. To obtain these slight concessions the profession must organise and become loudly vocal, and we look to the medical press to aid us powerfully to become so.

I am, Sirs, yours faithfully,
A. H. Bampton, M.D. R.U.I.
Ilkley-in-Wharfedale, April 10th, 1901.

"THE TEACHING OF ANÆSTHETICS."

To the Editors of The Lancet.

Sirs,—In The Lancet of April 6th, p. 1041, Lieutenant-Colonel Edward Lawrie, I.M.S., complains that he has been attacked "for hampering the important question of making the teaching of anæsthetics a recognised part of the medical curriculum by introducing side issues." It cannot fail to impress the reader of his remarks that his letter emphasises the justice of the strictures which have been passed upon him when he proceeds to give an entirely imaginary description of the clinical teaching of anæsthetics in the London hospitals. As long as 11 years ago my own fellow-students were most thoroughly taught and clinically trained by Dr. F. Hewitt at Charing Cross Hospital. After a series of lectures we administered a number of anæsthetics ourselves under his supervision, were encouraged to attend as many cases as possible, and were only granted a certificate of proficiency when he was satisfied that it had been deserved.

Dr. Hewitt's teaching began long before this, and has continued on the same lines to the present day. The anæsthetists at all the London hospitals with teaching schools now follow the plan of making the students themselves administer the ether and chloroform to as many patients as is practicable, so that Lieutenant-Colonel

Lawrie's burlesque account of the facts only weakens his other unsubstantiated statements His statistics (?) are as remarkable as the question he asks, "What is the use of calculating the ratio of deaths to population and not to the operations in which the various anæsthetics were administered?" when it is preceded by a statement that the deaths among his own dental chloroform administrations were *nil* in 15 years Perhaps it might be permissible to inquire whether he has administered chloroform in dentistry at all, as the absence of a number of *administrations* might conceivably result in an absence of mortality.

"*Hyderabad methods*" of inducing chloroform narcosis seem to have undergone a radical change since March 20th, 1899, when, according to Lieutenant-Colonel Lawrie's book on Chloroform, a death took place during the struggling stage of anæsthesia and he laid down the law "never to give chloroform while there is struggling and irregular breathing." "Formerly"—i e, previously to this date—he says, "there was always an element of chance and, consequently, of risk in the administration" "Hyderabad methods," then, were not so perfect from 1892 to 1899—in fact, for those seven years it would almost have been as safe to have inhaled chloroform at the hands of a London anæsthetist—but we can hardly expect Lieutenant Colonel Lawrie to admit anything involving so little prejudice —I am Sirs, yours faithfully,

H BELLAMY GARDNER, M R C S. Eng,
L R C P Lond,
Anæsthetist to Charing Cross Hospital; Assistant Anæsthetist to the Dental Hospital of London
Beaumont street, W, April 9th, 1901

To the Editors of THE LANCET

SIRS—Lieutenant Colonel E Lawrie makes the statement that in London "there is no practical teaching in anæsthetics worthy of the name' He adds his idea of what the teaching consists and again tells us how he teaches in Hyderabad It is perhaps a pity that before making such a sweeping statement Lieutenant Colonel Lawrie should not have ascertained what is really taught in London. At University College Hospital the students have actual control of, and responsibility concerning, the patient from the induction to the end of narcosis, being only supervised by the authorised instructor Careful and comprehensive notes are taken before, during, and after narcosis I have little doubt a similar course is adopted elsewhere The period of chloroformist clerkship is one month, which, as Lieutenant-Colonel Lawrie thinks, is more than sufficient for the average student I am, Sirs, yours faithfully,

Mortimer street, W DUDLEY W. BUXTON

"THE STATISTICS OF GASTRIC ULCER, WITH SPECIAL REFERENCE TO GASTRIC HÆMORRHAGE, ITS FREQUENCY AND FATALITY"

To the Editors of THE LANCET.

SIRS,—I fully agree with Dr Byrom Bramwell that the questions in discussion between us are of the greatest practical importance to the profession and I feel sure that Dr Bramwell's criticisms are advanced with the view of arriving at the real facts, which aim I also have only in view If, however, Welch's figures, based on observations on 32,052 necropsies, cannot be allowed as a basis on which to support arguments with regard to the frequency of gastric ulcer it is useless giving any further authority, for so far as I am aware no one has made observations on anything like such a series of cases, and we can only wait for Dr Bramwell's figures, which we shall hail with gratitude if they are based on post-mortem evidence As to the death rate in gastric ulcer I have not used the 50 per cent mortality suggested by some of the authorities named, but have halved that figure, which is considerably under the mean of the extremes, and I do not think that it is an exaggerated estimate to say that 1·25 per cent of the population die directly or indirectly as the result of gastric ulcer

I would once and for all point out that in my paper I never said that Leeds had a population of 500,000 or referred to Leeds itself except in the following words "Its importance will be better grasped if these figures are applied to the population of a city *like* Leeds, which for convenience I will take at 500,000"—taking the figure of 500,000 merely for convenience in working out the sums and referring to Leeds merely because its population nearly approached the number named and gave to the mind's eye a city of approximate size to the one referred to I am quite aware that the authorities I have referred to differ in their mode of calculation as to percentages of deaths from hæmorrhage, some referring to the percentage of deaths in all ulcers and others to the percentage of deaths in those ulcers that *bleed*, *but my own views are not indefinitely stated*, as the figures quoted by Dr Bramwell from my address show I said "7 per cent of deaths in cases of gastrorrhagia from ulcer will not be far from the truth. If this is worked out in the 500,000 population of a city like Leeds it means that of the 25 000 persons who have or who have had ulcer, 12 500 suffer from hæmatemesis and of these 7 per cent, or 875, die" Yet after making this quotation correctly Dr Bramwell *deliberately adopts other figures* in the very next paragraph of his letter, doubling the percentage of deaths from hæmatemesis, and he then proceeds to criticise the figures which he himself is responsible for.

In order that it may be quite clear both to Dr Bramwell and to those who are interested in the discussion I will put my figures succinctly I argued (1) that 5 per cent of the population suffer or have suffered from gastric ulcer, which therefore gives 25,000 in a population of 500,000, (2) that 25 per cent of those suffering from gastric ulcer *die directly or indirectly from the* disease, which gives 6250 in a population of 500,000, or 1 25 per cent of the population, (3) that 50 per cent of cases of gastric ulcers bleed, which gives 12 500 in a population of 500,000; and (4) that 7 per cent of cases of hæmatemesis from ulcer, or 3½ per cent of all persons suffering from ulcer, die as the result of the bleeding, which *gives 875 in a* population of 500,000, or 0 175 per cent of the whole population So far as hæmorrhage is concerned, if these figures are worked out for a year on the basis suggested by Dr Bramwell, that 20 05 per 1000 of the population of Leeds die annually from all causes, which means spreading the stated number of deaths over 49 87 years, or for convenience I would say 50 years, it means that in a population of 500,000 (875 – 50) 17 5 patients die each year from hæmorrhage due directly or indirectly to ulcer of the stomach

The following are the references which Dr. Bramwell asks for Müller, quoted by Savariaud (Thèse de Paris, p 51): "Of 127 ulcers, 37 hæmorrhages noted, of which 14 were fatal, which gives the great mortality of 11 per cent" Welch "Pepper's System of Medicine," vol ii Brinton: "Treatise on Ulcer of the Stomach and Diseases of the Stomach" Debove and Rémond "Traité des Maladies de l Estomac, Paris" "Ulcère de l'Estomac" Also quoted by Einhorn Steiner "Virchow and Hirsch's Jahresbericht, 1868," p 125 Quoted by Leube in Ziemssen's Handbuch and referred to in Savariaud's Thesis "In 110 cases there were seven fatal hæmorrhages, which gives 6 36 per cent" Lebert, quoted by Dreschfeld. "252 cases observed, 3 per cent *fatal from hæmorrhage*" Dreschfeld. "Clifford Allbutt's System of Medicine" vol iii, p 541 Rodman, *Philadelphia Medical Journal*, June 9th, 1900 p 1303: "Hæmatemesis occurs in at least 50 per cent of all cases of gastric ulcer, and many authorities estimate it as present in 80 per cent It is, too, fatal in 8 per cent of the cases in which it occurs, according to the conservative estimate of Leube. (*Archiv für Klinische Chirurgie*, 1897), and we cannot question that it is indirectly fatal in a much greater number of cases by anæmia and its remote consequences"

Until *Dr* Bramwell can furnish the profession with figures [illegible] distinctly prove or disprove these statements I [illegible]

[illegible]

Park square, Leeds April 6th, 1900 A W MAYO ROBSON

THE INDIAN MEDICAL PROFESSION.

To the Editors of THE LANCET

SIRS,—I was more than surprised to see in a late issue an unjust attack by your correspondent on the natives of India I regret that he should have been so short-sighted as to state that "the feeling in the service is that there are too many natives in it already, and that any further concession in their interest would be undoubtedly unpopular." As a matter of fact, it is a very high average if two Indians get in perhaps in a total of between 14 and 20. At each competition the Government do their best to exclude them by holding examinations in London. Notwithstanding this Indians risk the perils of the deep, leave their hearth and home, and everything that is near and dear to them, to spend a number of years in an inhospitable climate, and spend a large sum of money on the off-chance of succeeding in a proverbially uncertain competition, and that, too, in a foreign language. Yet they are grudged the few places which they now hold. Imagine the Chinese filling most of the hospital and service appointments in Great Britain How would the people here like to be told that the few Englishmen who wrested some appointments from the Celestials had done something which was unpopular and that "any further concession in their interest would be unpopular"? No, Sirs; the boot is on the other leg. If we are to make any complaint (which I do not make so long as a fair competitive examination is held in England and India) it is that there are too many Englishmen in the Indian Services. Your correspondent *further says that the Indian degrees are "not to be compared* to the British ones." Whose fault is it? No one has ever dared to say that the Indian intellect is a whit inferior to that of other nations. Therefore the fault must rest with those who mould that intellect. We want in India teachers to be recruited from all quarters, not, as is the present custom, to take them simply from the Indian Medical Service which thus enjoys a close monopoly. This system excludes some of the most brilliant amongst our profession who have no desire to go through an army medical examination. We can only appeal to fair-minded Englishmen to preserve the legitimate interest of an Englishman without robbing their Indian fellow citizens of their inalienable rights as judged by the chivalrous sense of British justice.

I am, Sirs, yours faithfully,

SARAT K. MULLICK.

New Cavendish-street, Cavendish-square, W.,
April 6th, 1901.

"THE ELIMINATION OF ARSENIC THROUGH THE HAIR."

To the Editors of THE LANCET.

SIRS,—You published in THE LANCET of April 6th, p. 1044, a letter from Dr. A. Dupré which refers to the possibility of arsenic obtaining entry into the hair through the medium of the perspiration emanating from the scalp. The fact that the experiments referred to in our article in THE LANCET of March 23rd, p. 854, were all made with recent hair, and the knowledge that our beer patients had ceased taking in arsenic for some little time previously to the samples being obtained, should be sufficient to show the unlikelihood of the hair being contaminated in this way. We may further point out, however, that the hair of all the arsenical patients was regularly washed, and that particularly in the case of the patient taking the drug medicinally this occurred every day.

Dr. George Pernet, whose letter you publish in the same issue, does not, we fear, thoroughly grasp the scope of our article. We were very careful to point out that the affinity of arsenic for the skin and its appendages is common knowledge, and we certainly made no claim to have discovered the "fact that arsenic is stored up in the hair and nails." We confirm previous observations and go a step further. We clearly show that arsenic can not only be detected in the hair of people taking the drug, but that the quantity in any given sample can be estimated with perfect accuracy by the method indicated in our paper, and further demonstrate the use which this knowledge can be put to as an aid to the diagnosis of arsenical poisoning. It is necessary that Dr. Pernet should discriminate between the value for scientific purposes of an accurate estimation of the quantity of arsenic to be found *in a weighed sample of hair and the mere detection* of the drug in this appendage.

We are, Sirs, yours faithfully,

E. KNECHT.
W. F. DEARDEN

Manchester, April 8th.

"THE ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—I am surprised that the secretary—who as an official of the hospital should, I think I am justified in saying, be publicly neutral—has obtruded himself into this matter. I am, however, glad because it enables me to acknowledge an error of information of which I might otherwise not have been aware, as I asked at the railway station for a copy of THE LANCET and could not get one. The secretary and the assistant secretary will tell you that I have always desired to be most accurate in this question of site, but unfortunately, I presume, through having read the letter without glasses, I overlooked a nought—a very important thing in figures, I admit. I have just re-read the letter and the word "sale" is not used, so I concluded that the offer was £1200 a year for leasing the Hanover-square part, as we have had several offers for leases. I readily apologise to you and all whom it may concern for that which everyone must see was a purely unintentional oversight. Obviously no one would desire to prejudice a good cause by purposely making incorrect statements. But this oversight in no way affects the real points at issue which are: (1) that £37,700 is considerably below the present value of the site; (2) that there is not the slightest necessity to part with our valuable property, which is increasing in value yearly as testified by experts; (3) that we are living rent free; (4) that partially building on our present site, even if we borrowed the money to do so, would increase the hospital's income £500 a year; and (5) that if it were necessary to do so we could rebuild the entire hospital on its present position, a magnificent one, for some £12,000, according to a letter which I read at the annual meeting in February last from a well-known firm of architects who have built another hospital. All these great advantages it is proposed to sacrifice for no sufficient reason which has yet been furnished in order to enter on a career of very uncertain future and full of grave and totally unnecessary risks. In my judgment and that of other members of the committee and several governors this is not the cautious policy which should govern so very serious a matter as the moving of a long-established hospital and the selling of its only property.

About two years ago Sir J. W. Ellis valued the site at £36,000; about a year ago two experts valued its leasehold price at £1500 a year; and at the annual meeting last year I read a letter from a well known firm of valuers stating the then value of the site to be £42,000. Since that time the value of the site has enormously increased and will increase, as proved by the fact that two years ago only £28,000 were offered and now an offer of about £10,000 more is made and accepted so far as the majority of the committee is concerned. Some two years ago the adjoining property, which is only two feet wider, sold for between £56,000 to £60 000, and shortly before that the property extending from Hanover-square to Oxford-street, facing that which is now being built on, fetched, I am informed, some £65,000 to £70 000. In view of the enormous increase in value of property in this position I think anyone caring to inquire will find that the market value of our site is from £45,000 to £50,000, and to let some £2000 a year, and its real value much greater. But as there is not the slightest compulsion to sell, as £2000 have been spent in putting the hospital into thorough sanitary condition, as from the point of view of further enhancing the value of the hospital's property we should remain where we are and for several other important reasons, we have nothing to do with market value or the highest offer Our duty clearly is to hold our piece of land and to increase our income by rebuilding the Oxford-street portion, or to leave well alone. I should add that though the choice of a proper site for a hospital is obviously a professional matter the views of the medical staff have been ignored, and though I have repeatedly given the committee credit for doing what they think to be best—though many believe them to be grievously mistaken—they have never even hinted that I and those who agree with me have the best interests of the hospital at heart. I have been and am fighting a very *difficult battle against rich men and as a consequence* have made many enemies, but I am conscious that I am doing that which can be shown to be best for the hospital. I have had valuable advice from experts in accounts and in building operations and valuations, and until the arguments which I have adduced can be controverted—and hitherto they have not been—it is my duty, I believe, to continue the contest, though I am fully aware that there are more kicks than thanks in the matter As to the secretary's remarks about the conduct of the committee I have repeatedly stated that, if forced, I reserved the right to do that which I thought or was advised was best in the hospital's interest, and should you desire further information on this point I shall be happy to furnish it

I am, Sirs, yours faithfully,

April 8th, 1901. THE SENIOR SURGEON

KOVCRYNSKI AND JOWOVSKI'S TEST.

To the Editors of THE LANCET

SIRS,—I should feel obliged if you or any of the readers of THE LANCET will tell me if they have found the above test for blood in the fæces a reliable one, and, if so, what special precautions are necessary in applying it My reason for asking is that on two or three occasions blood was declared present in specimens submitted to this test, whilst portions of the same evacuations submitted to possibly this amongst other chemical and microscopical tests by other persons gave negative results as far as blood was concerned The case is one of supposed duodenal ulceration with dark scybalous motions I am, Sirs, yours faithfully,

April 9th, 1901. M D

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Census in India —The Plague Epidemic,—The Pasteur Institute — The Tata Research Institute — Victoria Scholarships to Provide Native Midwives —Malta Fever — Malaria Epidemics

THE further census returns show more unexpected alterations The Bombay Presidency has actually declined by 1,500 000 It is this province which has suffered so severely both from plague and famine Bombay city has declined by 50,000 The proportion of males to females—about two to one—is the same as in Calcutta During the past four years in Bombay over 100 000 people have died above the normal rate and the birth rate has been reduced owing to the absence of females Calcutta, on the other hand, has increased enormously, the population in the municipal area now amounting to 843,487 The suburban areas with Howrah bring the total population on the banks of the river to over 1,000,000 The city of Karachi has increased by 10,000 and shows a population of 104,856 The city of Rangoon surpasses in growth all other cities and shows an increase of over 50 000 during the past ten years It has now 232 326 inhabitants The census of the aborigines in the Andaman Islands has been taken for the first time It shows a population of 24,499 Some considerable difficulty was experienced at one or two of the islands and attacks were made on the registering parties The population is probably under estimated.

Again this week I have to record a great rise in the pla[illegible] there were 7879 deaths Of [illegible] occurred in Bengal and 207 [illegible] disease has made its appearance in Kashmir, where several deaths have been reported The deaths in the various towns and districts chiefly affected are as follows: Bombay city, 1275; Calcutta, 557, Patna, 2070, Belgaum, 223; Dharwar, 51, Thana, 96; Surat, 24; Saran, 974; Monghyr, 358, Gya, 685, Durbhanga, 126, and Shahabad, 147 In the North-West Provinces and Oudh, including the city of Benares, there were 417 deaths from plague In Calcutta the disease is rapidly increasing and the published returns for the first two months of the year show a case mortality of over 90 per cent Of the total attacks about 20 per cent were seen by the authorities during life, the remainder being estimated after inquiry as due to plague Very few cases go to hospital—the people die in their own homes Beyond disinfection of premises no o [illegible] are being carried out In [illegible] to have attained its height [illegible] of the city is very heavy One district gives 345 per 1000 per annum, and 11 districts are over 200 All races except Europeans show a high mortality.

The work of the Pasteur Institute at Kasauli has proved very successful Since its opening 173 patients have been treated with results equal to those obtained at the Paris institution There have been as patients 15 British officers and 45 soldiers and one native officer and nine men, also 27 European civilians and 73 native civilians Many of the natives have been well educated men

The Tata Research Institute has had a severe rebuff in Professor Ramsay's report Without more money the institute could not be made to the scale of the original proposals Professor Ramsay unhesitatingly selects Bangalore as the site of the proposed institute, but expresses the opinion that unless the committee obtain a substantial addition to Mr Tata's donation Mr Tata would be well advised to withdraw his offer, The report is very full and considers the branches of learning to be pursued and the industries likely to be benefited as well as the financial prospects That it would be of value if established there can be no question, and it is earnestly to be hoped therefore that the means will be forthcoming.

Lady Curzon's fund for founding Victoria scholarships which will facilitate the training of Indian midwives promises to be a success Some of the wives of native princes and Indian ladies have supported it freely The scheme is an excellent one and will probably have marked results in lessening the sufferings of Indian women of all classes The mortality of women in childbed is at present great and puerperal fever is extremely common These scholarships once founded will endure and there will be no necessity for periodical appeals

The existence of Malta fever in India has been already alleged on several occasions Now it has been shown to exist in the Swat Valley An American writer has also recently stated that it is not an uncommon disease in Manila

Malaria epidemics have been recorded at different times, but until the establishment of the mosquito theory there was no satisfactory explanation to account for them It is suggested that an unusual rainfall in a naturally dry area creates pools in which the mosquitoes breed freely and that an epidemic of malaria is accompanied by a swarm of mosquitoes Where the fall of rain is excessive pools and other collections of water are washed so boisterously that the breeding-grounds are destroyed and thus it is not until after the rainy season that malaria becomes prevalent The outbreak of malarial fever in the Punjab last autumn is given by Colonel Bamber as an instance. There was an unusual rainfall last year, and notwithstanding the dry climate there is always a certain amount of malarial fever, so that when the mosquitoes had additional opportunities to breed they had material to disseminate the disease On the other hand, normally wet places might prove more dangerous during a comparatively dry season or an unusually small rainfall

March 15th

The Census of India —The Continued Famine and the Scheme for Future Relief Works —The Epidemic of Plague — Short Sight amongst the Natives

The rough results of the third general census of India taken on the night of March 1st have been published with wonderful promptitude The full totals were published a fortnight after the enumeration and they show that the population of India, including native States and territory enumerated for the first time, has increased from 287,317,048 as estimated in 1891, to 294,266,702, or 2 42 per cent Deducting the tracts enumerated for the first time the increase is reduced to 4,283 069, or 1 49 per cent This is a great decline from the 11 2 per cent in the previous decennial period There has been a diminution of 4 34 per cent in the population of native States, which is now estimated at 63 000 000 On the other hand, the population in British India has risen by 4 44 per cent and is now estimated at 231,000,000. The small rate of increase for India as a whole is unexpected and is attributed to successive famines and the plague The heaviest decreases are recorded in Rajputana, Central India, and the Bombay native States which have recently suffered so severely from the famine and which are now estimated to have lost at the lowest computation no less than 5,000,000 of their inhabitants The Bombay Presidency records a decrease of 627,000 and the Central Provinces a decrease of nearly 1,000,000. Bengal, on the other hand, shows an increase of 3,500,000, Madras an increase of 2,500,000, and the Punjab and Burma an increase of 1,500,000 each. The following totals for the various provinces and for the native States are now published:—

INDIA.

—	Males.	Females.	Total.
Ajmere-Merwara	250,721	225,609	476,330
Assam	3,142,561	2,979,640	6,122,201

Bombay States	3,504,975	3,386,716	6,891,691
Madras States	2,100,313	2,090,009	4,190,322
Central Provinces States	932,823	1,000,673	1,933,496
Bengal States	1,899,704	1,836,011	3,735,714
North-west Provinces States	411,897	387,778	799,675
Punjab States	2,417,932	2,020,884	4,438,816
Burma States	609,695	618,665	1,228,460
Total (Native States) ...	32,465,697	30,715,872	63,181,569
Total (all India)...	149,906,349	144,360,352	294,266,701

The following table shows the net increase and decrease of population, as distinguished from the percentage of increase or decrease, in the various provinces of India:—

Assam	+688,000	North-west Prov. States	+7,000
Bengal	+3,366,000	Punjab States	+175,000
Sind	+341,000	Ajmere-Merwara	−66,000
Upper Burma	+487,000	Berar	−144,000
Lower Burma	+962,000	Bombay Proper	−627,000
Coorg	+7,000	Aden	−2,800
Madras	+2,578,000	Central Provinces ...	−938 000
North-west Provinces...	+558,000	Hyderabad	−362,000
Oudh	+233,000	Baroda	−464,000
Punjab	+1,582,000	Rajputana	−2,175,000
Mysore	+594,000	Central India States ...	−1,816,000
Kashmir	+362,000	Bombay States	−1,167,000
Madras States	+489,000	Central Provinces States	−177,000
Bengal States	+439,000		

The famine relief figures for last week show that there are still 220,400 persons on the lists, of whom 176,400 are in Bombay and 39 400 are in native States. These returns show a decrease of 3000 compared with the preceding week. A resolution of the Government recently published says that there is a general consensus of opinion that famine labour might be turned to better advantage if more systematic endeavour were made in ordinary times to plan out works which, though they may not be strictly remunerative, would at least be of some permanent utility. Great irrigation works on a larger scale are required in many districts. It is proposed to construct works, chiefly in the Punjab and Sind, calculated to irrigate nearly 4,000,000 acres. Irrigation works of a "productive" character will also be extended in the famine areas and will be commenced during the coming winter, and elaborate surveys and preliminary estimates will be prepared for future operations. It is evident that the present Viceroy is taking active steps to combat the difficulties of any future famine.

The plague figures still mount up. The number of deaths throughout India for the week ending March 16th has reached a total of 8829, against 7700 for the previous week and 4725 for last year. Bengal alone reports 4871 deaths. The disease, hitherto confined to the western districts, is spreading to others. Patna district records 2529 victims, Saran 1291, and Monghyr 431. The plague mortality in Calcutta has risen from 557 to 819, the total attacks being nearly 1000. The disease is increasing in the North-west Provinces, and is spreading in Ghazipur, Ballia, Jaunpur, and Benares, so that there is an area of large extent in the central Gangetic valley which is attacked. The area of greatest severity is shifting, and curiously the country intervening between the boundaries of Bombay and Benares is quite free. Bombay city during the past week records 2492 deaths from all causes and 1203 deaths from plague. The outbreak in that city seems to be at its height. Karachi is showing a rising mortality, and there are many more villages in the Punjab which have been recently attacked. Altogether the outlook is gloomy. So far inoculation seems to be the chief successful agency in controlling the disease, but it is not sought after. Neither in Bombay city nor in Calcutta is it being practised except to a very limited degree, but in the Patna district and in the Punjab it is being taken up readily. It is the old story of shutting the stable door after the horse has been stolen.

The subject of short sight among the natives of India has been recently commented upon by Captain Elliott. He describes the natives as preeminently a studious race and says that they carry their worship of book-learning to a fault. He states that the defects of the eye among Indian children greatly outnumber those among European children, "for not only have they the same anomalies of refraction to cope with but also the results of small-pox and various forms of ophthalmia." He thinks that India will not escape the evil which has appeared in every great centre of education in the world. This short sight increases with the age of children and is almost absent in the case of the younger pupils. Notwithstanding the improvement in schoolrooms and methods of instruction the evil even amongst the nations of the West still continues and the danger, therefore, to the Indian native from his increased book study has become serious. Captain Elliott's warning is very opportune. The increased use of glasses in India, especially by the Parsees, is a matter of daily observation.

March 23rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

THE annual meeting of the Manchester and Salford Sanitary Association was held on March 29th in the Town-hall, Professor J. Dixon Mann being in the chair. The report dealt with lamp explosions, horse ambulance for the city, the price of gas, the proposed State Public Health Department, the proposed hospital for cases of infectious disease, cottage baths, the improvement of slums, and beer-poisoning. If the power of the association were in proportion to its zeal and goodwill in the cause of sanitation there would soon be an improvement in the public health. It is indeed remarkable how much has been done in educating public and municipal opinion with very small pecuniary support. The income last year was just a little over £140. The Smoke Abatement League—affiliated with the association—referred in its report to the recent increase in the price of gas as a retrograde step on the part of the Corporation. It checked and delayed the use of gas instead of steam as a motive power and instead of coal for heating and cooking purposes, and hence delayed the greater freedom from smoke and the more cleanly state of the air which would result. The cheapening of gas would lead to its greatly increased use by those requiring power on a small scale and a small steam-engine is a greater smoke producer in proportion to the work it can do than a large one. It would also ensure the full use of the gasworks, even though electric lighting should become cheaper and more popular for domestic use. Salford for years has lagged behind Manchester in its efforts to lessen the smoke nuisance, but Mr. C. H. Tattersall has recently given a warning to offenders, and if the Salford Health Department should become as active in its repression as the Manchester Corporation Committee there would be more sunshine and brighter days in both these smoke-begrimed towns. Professor R. B. Wild proposed a resolution approving of the work of the association, the Smoke Abatement League, and the Ladies' Health Society which is always doing good work. This was seconded by Dr. Sawers Scott. But as towns grow rapidly, Canon Richardson did well to draw attention to the increase of "small property" in Fallowfield and Levenshulme, where, in his opinion, slums were being manufactured which would in time be as great an evil as those in the city. It is easy to make slums, even in the open country. A builder will run up a few rows of thin-walled cottages that prop each other up, in close proximity or back to back, stuck on the bare ground without drainage and with very imperfect sanitary arrangements, and the people who gravitate to such shelters will soon make them fairly entitled to be called slums. It has often been done, and in spite of building laws will no doubt be done again. Dr. Vivian Poore gave an interesting address on the sanitary advantages and disadvantages of the modern city. He advocated the burial of organic matter and said that if it were thoroughly carried out there would be fewer house flies and rats, and that "it should serve as an object-lesson to the whole country that the value of Carrington Moss had risen from 1*s.* to £2 10*s.* an acre by the addition to the soil during the last nine years of the sewage of Manchester." This is true if the word "night-soil" is used instead of sewage. Professor Dixon Mann was elected chairman of the committee and Dr. F. J. H. Coutts an honorary secretary of the association.

Views on Scarlet Fever.

In the annual report as to the health of Haslingden Dr. J. A. Harrison, the medical officer of health, has had the courage to express views which, if held by others of his brethren, are not always given to the world. He says he is of opinion that the best thing that can happen to a child is to have scarlet fever whilst it is young and when life is not of the same vital importance as after it has become a father or a mother of a family. If he has not had the disease a person may contract it, and, "as a general rule, children have it in a milder form than adults and are more likely to recover"

Workhouse Nursing

Mr. H. Jenner-Fust, Poor-law inspector for Lancashire, Westmorland, parts of Cumberland, and the West Riding of Yorkshire, in his latest return of the number of workhouse inmates in his district under medical care at the beginning of this year, exclusive of imbeciles and epileptics in special wards, says that the increase of nurses has kept pace with the increased number of sick, but that in several instances there was great need for more night nurses and for the "lessening of the number of paupers employed under the name of attendants." In the Manchester township the patients were 1064, with 78 day and 22 night nurses in attendance Chorlton Union had 746 and 49 day and 24 night nurses Five day and two night nurses were in charge of 147 patients in the Prestwich Union, whilst in the Salford Union Hospital at Hope 495 patients were cared for by 31 day and 11 night nurses. The Lancashire workhouse patients at the beginning of January were 9374; the nurses numbered 744, in addition to 148 pauper assistants.

The King and the Manchester Royal Infirmary.

A letter from Whitehall was received on April 4th at the Manchester Royal Infirmary in which it was stated that the King had been pleased to accede to the application of the Board of Management that the institution be designated the Manchester Royal Infirmary, Dispensary, and Lunatic Hospital or Asylum. The letter also sets forth that the application of the board for the continuance of Royal patronage has been referred to the Keeper of His Majesty's Privy Purse.

Heaton Park.

Manchester seems to be within measurable distance of purchasing Heaton Park and when one thinks of its poverty in large open spaces as compared with many other cities and of the rapidity with which its suburbs are becoming covered with bricks and mortar one cannot but feel that it would be a calamity if the opportunity of securing it were lost. It contains about 680 acres, is elevated, its surface is undulating, and it is very near the city boundary. It is, moreover, the last open space of large extent "with any pretentions to natural beauty in the outskirts of Manchester that is still unspoiled by the builder." The corporation seems to be in earnest this time and yet when the Trafford Park fiasco comes to mind the fear will arise that after all they may let it slip The hope expressed by Alderman Southern that "a similar mistake would not occur in this instance" will be widely echoed in Manchester. It may, perhaps, be assumed that syndicates and those through whom they act are not troubled about questions of ethics.

April 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

The late Deputy Surgeon General Fleming.

THE death occurred in Edinburgh on March 25th of Dr. Andrew Fleming, Deputy Surgeon General Indian army. Dr. Fleming was the son of Dr John Fleming, Professor of Natural Philosophy in the University of Aberdeen, and afterwards Professor of Natural Science in the New College, Edinburgh The late Dr Andrew Fleming obtained the degree of M D. in Edinburgh University. When assistant surgeon of the 4th Regiment Punjab Cavalry he was recommended to the Indian Government as a geological surveyor by Sir Roderick Murchison. He drew particular notice to himself by his report on the geological structure and mineral wealth of the salt range in the Punjab, published by the Government of India 1851–52 He also contributed to our knowledge of the fossil fauna of India. On retiring from active service he took up his residence in Edinburgh. He is survived by a widow, three sons, and three daughters. His sons are all at present engaged in His Majesty's service abroad.

Glasgow University.

The half-yearly meeting of the general council of Glasgow University was held on April 3rd On the motion to adopt an appropriate address to the King the Rev David Macrae desired to enter a protest against the selection of the title "King Edward VII" on the ground that it implied that the six English kings of the same name had ruled over Scotland and was therefore historically inaccurate The Principal, however, declined to accept the protest A similar position was taken up recently at the Convention of the Royal Burghs, the objector here being Dr Donald Munro, formerly lecturer on Forensic Medicine in the University of Glasgow. The business of the General Council on the present occasion was mainly concerned with the arts faculty. The report of the Business Committee included an elaborate argument in favour of extending more complete university recognition to modern languages This was adopted by the council and an endeavour is to be made to secure simultaneous action in all the Scottish universities. The committee having charge of the erection of the Caird Memorial Window reported the completion of their task and announced that a balance of nearly £50 had been spent on the purchase for the library of some theological works to be especially associated with the late Principal's name During the last week the professional examinations for degrees in medicine have been held The completion of these has left the medical quadrangle empty The summer session is to commence in a fortnight's time and some special arrangements of examinations and other work are contemplated in order to permit the doing of full justice to the academic ceremonies which are to celebrate the occurrence of the University's ninth jubilee.

St Andrews University.

The annual graduation ceremony which closes the winter session took place on April 2nd The ceremony was distinguished at the outset by the fact that the historic "cap" which formally converts the graduand into a graduate, was at the critical moment not to be found Fortunately it was soon discovered and all then went well The honorary graduates included Mrs Agnes Smith Lewis and Mrs. Margaret Dunlop Gibson of Cambridge, these being the first ladies to receive the compliment of an honorary degree from this university. Professor Alexander Agassiz of Harvard College and Professor J. A. Ewing of Cambridge also received the honorary degree of LL.D.

Small-pox in Glasgow.

The new cases of small-pox admitted during the week number 50. The total under treatment in hospital on April 7th was 234. The revaccination crusade continues to be energetically pressed and on the whole with encouraging results. The epidemic has been so wide in its distribution and the practical handling of it has presented such unusual difficulties that it is impossible to expect a sharp or sudden termination of its course. The diminution of cases in hospital shows that steady progress continues to be made. At a recent meeting of the Lunacy Board an attempt was made to suggest to the General Board that the condition of the small-pox epidemic justified the re-opening of the asylums to friends and other visitors. Dr. Bruce spoke strongly against this proposal which after discussion was negatived.

Medical Dispute at Kilmarnock.

An unfortunate dispute leading to strained relations has for some little time existed between the medical officer of health of Kilmarnock on the one hand and the Public Health Committee and sanitary inspector on the other. The medical officer has also had differences with some of his brother practitioners regarding the notification of cases of infectious disease. The whole of the questions involved have been brought to the notice of the Local Government Board and are now to be the subject of official inquiry. This is to be held in private.

April 9th.

IRELAND.

(From our own Correspondents.)

The Royal College of Physicians of Ireland.

His Excellency the Lord Lieutenant of Ireland has accepted the invitation of the President of the Royal College of Physicians of Ireland to attend a banquet which will take place at the College on April 29th.

Lecture by Dr. Kendal Franks.

A lecture of exceptional interest was delivered on April 9th, in the town-hall, Blackrock, by Dr. Kendal Franks, the subject being "From Cape Town to Pretoria with Lord Roberts." Dr. Franks was a consulting surgeon to the forces in South Africa and a member of the headquarters staff.

Alleged Murder by a well-known Medical Practitioner.

Much unpleasant sensation has been caused in Ireland by the tragic death of the wife of Mr. Edward T. French, F.R.C.S.Irel., of Glasson, co. Westmeath. It would appear that while labouring under an attack of maniacal excitement Mr. French attacked and stabbed his wife who died after a few minutes. The verdict of the coroner's jury was that the deceased died from wounds inflicted by the prisoner while under the influence of drink. A post-mortem examination made by Mr. H. Moorhead of Moate revealed a wound between the eighth and ninth ribs which penetrated the liver and reached as far as the heart. The deceased lady belonged to a very well-known family and was popular in society and in the hunting-field. Mr. French also, who is now lodged in Mullingar gaol, is a member of a highly respectable family in the west of Ireland.

Ulster Medical Society.

At the sixth meeting of the session held in the Museum, Belfast, on April 4th, Dr. H. L. McKisack called attention to the more extensive use that might be made of the society for providing nurses for the sick poor in Belfast. Dr. J. McLiesh read notes of a case of Cyanosis, and Dr. Lorrain Smith and Dr. McKisack described a case of Plethora associated with Adherent Pericardium.

County Down Infirmary.

From the treasurer's statement it appears that the total expenditure of this infirmary for 1900 was £1537 13*s*. 6*d*. After payment of accounts there is a balance of £281 16*s*. 7*d*. There are 454 intern patients, which number, with 36 remaining over from the previous year, makes a total of 490. The average number of beds daily occupied was 34, and the average cost of each patient was 2*s*. 5¼*d*. per day. The number of extern patients was 536.

Irish University Education.

At the present time the subject most commonly discussed in Ireland is that of the university question and it is felt that the whole problem has been thrown into the melting-pot by the action of the Government in appointing a Royal Commission to consider the matter. That the question is a most perplexing one is self-evident to anyone living in Ireland and already the Government must feel this, for even in reference to the Commission two points are being very freely debated: first, what are the questions to be considered? and secondly, who are to be the members? The Lord Lieutenant of Ireland, in his speech to the deputation asking for an inquiry into Irish university education, seemed to imply that Trinity College would be excluded from consideration; but this view has been received with adverse criticism, and resolutions have been sent to Lord Cadogan demanding that the affairs of Trinity College should be discussed, and, in truth, it is hard to understand how anyone can discuss university education in Ireland without referring to the Dublin University. To exclude such a subject would, indeed, make the results of the work of the Commission of very little import. Again, the question of who are to be the Commissioners must be a most difficult one. Two things are clear. They should be experts in education and they should not have committed themselves to any of the various views put forward as settlements of the Irish university question. If these matters are not attended to the labours of the Commission will, indeed, be in vain. I think that if a full inquiry is made, and if proper persons are selected as members of the Commission, a great deal of good will come out of this inquiry, and the proper attitude for all Irishmen should be to try to forget those sectarian and religious differences which have wrought so much evil in the country and to endeavour to evolve some solution of the university question which will bring contentment to the country. All parties feel that the present state of affairs is well nigh intolerable, and the total uncertainty prevailing as to the ultimate settlement of the question is in the meantime doing incalculable harm.

Water-closets or Privies.

A curious case came before the county court judge at the Lurgan Quarter Sessions on April 1st on an appeal from the local magistrates, who at the instance of the Lurgan Urban Council ordered a citizen of that place to provide properly constructed water-closets, dry ashpits, sufficient house drainage, and gulley-trap connexions, and to tile or to concrete the yards. The points at issue were, was the substitution of water closets—Lurgan has a splendid water-supply—for privies necessary and had the magistrates power to order such. Dr. S. Agnew (medical officer of health of Lurgan) and Sir Charles Cameron advised the substitution of water-closets and stated that the present sanitary arrangements in the houses were unsatisfactory. The latter made a remarkable statement—that "the reason why the typhoid fever rate of Belfast was higher than that of any other city or town in the United Kingdom, exceeding even Dublin, where it was mild in comparison, was the feeling against water-closets in Belfast." For the appellant, Dr. Charles O'Neill and Dr. H. R. Torrens of Belfast gave evidence that the privies were not nuisances in the particular cases referred to, nor were they, in their opinion, injurious to health. In giving judgment Judge Kisbey stated that in order to satisfy a court of appeal the onus was thrown on the respondents to satisfy the court that a nuisance existed. Therefore, going on the evidence of these Belfast gentlemen that no nuisance existed he would have to reverse the magistrate's decision. He refused costs in the case. The lesson of this judgment is that local sanitary authorities in Ireland cannot enforce the substitution of water-closets for privies. If the latter are defectively constructed or improperly kept they may enforce repairs or rearrangements, but property-owners cannot be compelled to convert privies into water-closets even in a town like Lurgan, where there is an unfailing water-supply (Lough Neagh). Evidently some change in the law is needed.

April 9th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Sciatica by Intra arachnoidal Injections of Small Doses of Cocaine.

AT the meeting of the Hospitals Medical Society held on March 29th M. Marie and M Guillain communicated the details of a case in which they had employed the above treatment The patient was a man, aged 35 years, who had suffered for the past eight days from right-sided sciatica of medium intensity for which no definite cause could be found. They gave him an intra arachnoidal injection of five milligrammes of cocaine. Three minutes after the injection the patient felt that the pain was much diminished, and six minutes after it had entirely disappeared and nothing remained but slight traces of Lasegue's sign. The patient then and there insisted on getting up, saying that he was cured. He dressed, went out, and he walked about all day. At 4 30 P.M. the pain came back, but only in a slight degree; the patient passed a good night, and the next morning, although he had a certain amount of pain, he said that it was nothing compared to that which he had suffered the day before. The relief has persisted to the present time M Marie and M. Guillain reminded the meeting that at the meeting of the Neurological Society held on March 7th, M. Achard had reported three cases of sciatica treated by injections of cocaine, but the dose was from one to two centigrammes. He seemed to think that a certain amount of anæsthesia must be produced in the legs if the treatment were to be successful. In their own case the dose was much smaller and did not exceed five milligrammes; relief was rapidly brought about and no cutaneous anæsthesia was produced If the foregoing facts definitely show that such small doses are efficacious this treatment will present manifest advantages, for there will be much less chance of those ill-effects arising which are sometimes noticed after the intra-arachnoidal injection of larger doses of cocaine.

Dramatic Representations in Lunatic Asylums.

Only recently a most interesting fête was held at the Lunatic Asylum of Villejuif. For some years past various artistes have gladly given their services for the amusement of asylum patients, but at Villejuif the asylum staff are not content with amusing the patients by the recollections which the plays call up, but they are anxious that the plays should be the work of the patients themselves. The text of the first pièce given on this occasion, *L'Agence Beauminet*, was written by a patient, the music was composed by another, while the whole of the costumes, decorations, &c., were the work of *costumiers* and the like who were patients. Every player looked after his own dress, and all the players were patients. One of the medical staff was appointed to act as stage manager and to guide all these good intentions into the right paths. It could not be denied that the art exhibited was somewhat elementary, but compensation for this was found in the life and spirit of the acting. One somewhat curious fact was noted by the medical staff—namely, during the time that the minds of everyone in the asylum were fully taken up with the great event mental crises were very rare. In the case of one patient, a certain "Madame le Diable," who only a month previously had had a terrible outbreak, the wish to act and to be able to be admitted to the *troupe* was so strong that it literally cured her. The professional playwrights decided, however, that they would edit the lunatics' work.

Taxation of Medical Men Practising at Watering-places.

An interesting debate took place in the Senate on March 27th on the discussion of a taxing Bill (*loi des patentes*) An amendment standing in the names of M Pozzi and M. Pédebidou which was accepted by the committee proposed that medical men who practised only at spas and watering-places and nowhere else should be assessed professionally (*payer l'impôt de commerce*) only in the watering-place where they practised during the season and not in the town where they lived for the rest of the year. M. Payolle, director-general of direct taxation and a Government commissary, opposed the amendment, alleging the following reasons for his action: (1) all business men are assessed not only for their business premises but also for their private residences; and (2) a watering-place practitioner who lives in Paris nine months out of the 12 spends profits there which he has easily made in the three months of his stay at the watering-place, and it is only fair that he should be taxed for the comfort and luxury in which the profits of his watering-place practice allow him to live. The Senate, however, thanks to the persevering efforts of M Pédebidou, did not agree in this view and decided that medical men could not be considered as being in the same class with others who have to pay a *patente* It accordingly passed the following resolution:—

[illegible]

man, but it would be still more gratifying to see the motion put forward by M Labbé accepted—namely, that the business tax (*l'impôt de commerce*) should not be levied except upon professional premises It is anomalous that medical men with large families who have of necessity to have a big house should be taxed much more highly than those who live just as well and yet are able to do with quite a small flat (*petit entresol*)

April 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Examination for the Government Medical Service.

NEW regulations concerning the examination for the Government medical service have just been issued. Medical men desiring to enter this service may present themselves for examination either two or three years after becoming qualified, according to the place obtained by them in the State examination. They have to produce certificates of attendance at lectures on forensic medicine, of attendance at a lunatic asylum for at least six months, and of having done practical work in a dissecting room, in a public health laboratory, and in an institute for forensic medicine at a German university for at least three months. Candidates must write two theses, one on a question of public health and the other on a question of mental pathology or forensic medicine The practical examination is divided into the following four parts. 1. Medical legislation: candidates must have a knowledge of the laws concerning public health, the regulations for the Government medical officers, &c. 2 Hygiene: candidates have to make an investigation on some matter of public health and to give a short explanation of the methods which they have employed 3 Forensic medicine: candidates have to examine an injured person and to draw up a detailed written report; they have also to make a post-mortem examination and to give an opinion as to the cause of death; finally, they have to prepare microscopical specimens and to describe them. 4 Mental diseases: candidates have to examine an insane person and to give a certificate on the case. Obviously the new regulations will not meet with general approval, though they are in accordance with the reform of the public health service already described in THE LANCET. It is a mistake to combine the functions of health officer and medical expert at law courts and to require from a medical man that he should have a thorough knowledge both of hygiene and of forensic medicine as well. The "reform" has, however, become law and the Government medical officers will therefore probably continue for a long time to hold this combined office.

Extension of Clinical Study in Berlin

The newspapers report that the Minister of Public Instruction has asked the Berlin Municipal Council to consent to one of the municipal hospitals being used for the clinical teaching of medical students When this event takes place it will mean the beginning of a revolution in clinical teaching Hitherto official clinical lectures have been delivered exclusively in the Royal university clinics which belong to the university and are under State control, the office of the director of the clinic being invariably combined with an ordinary professorship in medicine, surgery, obstetrics, &c. It is obligatory on medical students to attend the lectures of these professors, because they alone are entitled to give the certificates which are necessary for admission to the State xamination. The number of patients attending these linics, though considerable, is by no means sufficient for he increasing number of students and the practical work vhich a medical student is required to perform there ccording to the regulations has become little more than nominal. In the course of a semester the clinical "practicant" is asked once or twice during the clinical lectures to examine a patient in presence of the professor and the assembled students, and to answer some questions on the case. This is, so far as Berlin is concerned, the whole of the practical work for which opportunities are officially afforded by the university. Obviously this is far from sufficient for a man who intends to enter upon practice on the completion of his studies and the great majority of students have therefore tried to supplement their practical training by attendance on private practical courses. Such private courses have been in existence for a long time, not only in the university clinics but also sometimes in other hospitals and in private clinics, but they have not had any official connexion with the university. Undoubtedly the Minister of Public Instruction is quite right in trying to procure a wider field of clinical training for the Berlin students by bringing the other great hospitals into connexion with the university. The medical wards of the Moabit municipal hospital have in the first place been chosen for this purpose, and both the chief physicians of the hospital have been requested to deliver official lectures in clinical medicine to the students. As the hospital is not provided with a lecture-room it is reported that a large amphitheatre will be constructed on the premises on behalf of the university. It will be interesting to know whether the right to deliver official clinical lectures and to give certificates will be granted to the present chief physicians only or whether it will be connected with their office and thus be transferable to their successors. Similar arrangements will be made in other large hospitals, and the system of clinical teaching will probably come to resemble that of the Paris hospitals, which have always been used for clinical instruction under the control of the medical faculty of Paris.

Professor Virchow.

The eightieth birthday of Professor Virchow, the Nestor of medical science in Germany, will be celebrated this year. In honour of this event a committee consisting of the leading medical men of Germany and abroad, of other *savants*, and of men prominent in various ways, proposes to collect a fund to support the Rudolf Virchow Stiftung, an institution for the promotion of scientific research founded in 1881 on the occasion of the professor's sixtieth birthday. The document embodying the proposal has received about 600 signatures. The chairman of the executive committee is Professor Waldeyer Of the other members Professor Fraenkel, Professor Israel, Professor Posner, Professor von Bergmann, Professor Engelmann, Professor Eulenburg, and Professor König belong to the Berlin medical faculty. The Government is represented by Dr. Althoff, Director of the office of Public Instruction, and Dr. Pistor of the medical department; the army is represented by Dr von Coler; the city of Berlin by the mayor and the president of the town council; and anthropological science by Dr Bartels, Professor Bastian, Dr. von den Steinen, and Dr. Voss. The committee, moreover, includes Professor von Richthofen (president of the Geographical Society), Dr. Becher (president of the Berlin Medical Chamber), and others. Foreign committees will be formed in various countries. Lord Lister will be chairman of the British committee, Professor Wilson (Sydney) of the Australian Committee, Mr. Risley (Calcutta) of the British India Committee, and Professor Scott of the New Zealand Committee.

April 8th.

DUTIES OF SCHOOL BOARD OFFICERS.—An inquest was held in Bristol recently upon the body of a boy, aged eight years. He was ill in bed with bronchitis when the school board officer called at the house, insisted on his being brought downstairs, and told him to go to school in the afternoon. The child went to school, but soon had to return home, and died the same evening. Medical evidence showed that he was not in a fit state to be sent out of doors when the officer sent him to school and that death resulted from bronchitis. The jury returned a verdict to that effect and added a rider that the school board officer had exceeded his duty.

Obituary.

HENRY ERNEST HILL SMITH, M.R.C.S. ENG., L.S.A.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

MAJOR HENRY ERNEST HILL SMITH was born in the year 1861 and was the son of the late Mr. Henry Smith, one of the most distinguished London surgeons of his time. He completed his school life at Chatham House, Ramsgate, and in 1879 entered King's College Hospital, to which later he became house surgeon. He joined the Army Medical Department in 1887, being "first in and out" of Netley. Shortly after, being gazetted surgeon-captain, he applied to be put on the foreign roster and did duty at Singapore until 1891. In 1894 he was selected for service in the Egyptian Army. The commencement of the Dongola expedition in the spring of 1896 found him at Suakim where as senior medical officer he had for a year or more won golden opinions among the native population by his successful surgery. He soon was at the front at Akasheh, having crossed the desert with such of the Suakim troops as could be spared. He was with the cavalry and camel corps in the surprise of the Dervishes at Firket in June, 1896, and in the following year was senior medical officer of the flying column which, under General Hunter, seized Abu Hamad. All through the many engagements of the Soudan campaign he was senior medical officer to the mounted troops and did extraordinarily good service, receiving seven clasps to his Soudan medal and being mentioned four times in despatches; for his services in the Soudan he was specially promoted major in the English army and bey in the Egyptian army; he received also the Medjidieh decoration. As senior medical officer of the frontier he passed the greater part of the last two years of his life at Omdurman, Fashoda, and the south; he was among the first English officers to reach the Sebat river and had some excellent sport among hippopotami, elephants, giraffes, and various kinds of antelope, &c., in these hitherto practically unknown regions. He was, however, as senior medical officer of the frontier a very busy man, for epidemic diseases were very prevalent among the troops, malaria spared no one, he himself was often down with it, and was up with it more often, for he had to struggle on at times with his work when the whole of his staff were on the sick list. Among the many epidemics which he had to combat in the Soudan was a particularly fatal one of cerebro-spinal meningitis on which he wrote a valuable report which was published by the Director-General of the Army Medical Service (*vide* Report, 1898).

Major Hill Smith was a sportsman in every sense—keen, thorough in everything, he was essentially a "good all-round man." His bright, irresistible *bonhomie* was such that no one ever met him but felt the better for it—he had a sort of tonic effect; and the great charm of the man was that he was always the same, whether in cholera camp, in polo or cricket field, under fire, or nursing a sick comrade. He won the respect, the admiration, the trust, and the love of all. His sudden death subsequently to a fall from his horse in a jumping competition is the source of the greatest grief to all in Egypt who knew him The following special army order was published by the Sirdar of the Egyptian Army:—

"War Office, Feb. 24th, 1901.

"The Sirdar announces to the Army with deep regret the death of El Kaimakam Hill Smith Bey, Medical Corps, which took place at Cairo on the 22nd instant after a few hours' illness.

"Those who were brought in contact with him during the six and a half years which he passed in His Highness's service will remember how, by his unceasing cheerfulness and unremitting care of those in his charge he endeared himself to all, and the Sirdar feels that the whole army joins with him in mourning the loss of a gallant soldier and a beloved comrade."

CHRISTOPHER MERCER DURRANT, M.D. EDIN., F.R.C.P. LOND.

ON Easter Eve, April 6th, there passed away, at the ripe ld age of 86 years, Dr. Christopher Mercer Durrant, one of the oldest practitioners in the eastern counties. He was born in 1814 at Lewes, where he received his early education, and later went to Berlin to study German, going thence to the University of Edinburgh, where in 1839 he took his M D. degree In the same year he married and commenced practice as a consulting physician in Ipswich. He was elected after a time physician to the East Suffolk and Ipswich Hospital, in which institution he always took the greatest interest, and his long services there are still remembered with gratitude. A serious illness in 1879 obliged him to resign his active duties in connexion with the hospital, but he continued on its staff as an honorary consulting physician. He was the first President of the East Anglian Branch of the British Medical Association in 1843 and at their jubilee meeting held at Stowmarket in 1893 additional interest was given to the gathering from the unique fact that the President of 50 years before was again by universal consent nominated to the chair. He took a warm interest in the Ipswich Nurses' Home, as well as in the Suffolk Convalescent Home at Felixstowe, in both of which institutions he served on the committee. For several years he took a room in Cox-lane, where once a week the poor of the town and district could consult him and have the benefit of his advice gratuitously. He was a J P. for Suffolk and while health permitted was a regular attendant at the Samford bench. He has contributed several papers to the *British Medical Journal* and in 1873 he was elected Fellow of the Royal College of Physicians of London. The funeral took place on April 11th, the first part of the service being said in St. Margaret's Church, while the burial took place at Freston.

JAMES HOOPER, M R C S. ENG., L S A.

MR. JAMES HOOPER died at his residence, Odd Down House, Odd Down, Bath, on March 27th, in his ninety-sixth year. The deceased, who was the son of the Rev. Thomas Hooper, rector of [illegible] received his educ[illegible] was contemporary with Mr. Gladstone and attended the funeral of George III. He studied medicine at University College, London, and qualified as M R C S Eng in 1841, taking the diploma of L S A in the following year. Mr. Hooper was for many years in practice at Ford and was one of the district medical officers of the Chippenham Board of Guardians; he afterwards practised at Marshfield, near Bath, and was attending to some of his professional duties when 90 years of age Mr Hooper had a considerable reputation as a skilful surgeon and his opinion was often sought by his colleagues in the district The deceased leaves two brothers, who are 88 and 84 years of age respectively. The funeral took place at Yatton Keynell on April 1st.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced.—Dr. Theodor Wynen, Assistant in the Marburg Hygienic Institute, in consequence of infection contracted in the course of his work.—Dr. H Gosse, Professor of Forensic Medicine in the University of Geneva

Medical News.

SOCIETY OF APOTHECARIES OF LONDON—At the primary examination, held on April 1st, 3rd, and 4th, the following candidates passed in the subjects indicated:—

PART II.

Anatomy—H Bacon, Cambridge and Guy's Hospital; B F Board, Royal Free Hospital, J M Burke, Cork and Galway, P. Butler, Birmingham, W R Clarke, University College Hospital, E M Forsyth Royal Free Hospital, A. F. Heald, Cambridge H Leach, Leeds, D Mann, Royal Free Hospital, J A. Renshaw, Manchester; and J H. K. Sykes, Leeds

[illegible]

J. H. K. Sykes, Leeds, and J. M. Wall, St. Thomas's Hospital

UNIVERSITY OF GLASGOW—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M B) and Bachelor of Surgery (Ch.B) in the subjects indicated (B., Botany; Z, Zoology; P., Physics; and C, Chemistry):—

William Allan (P), William Smith Allan (P, C), Andrew Allison (Z, C), George Victor Anderson (B., Z), Donald Arbuckle (B, Z., C), Andrew Hamilton Arnott (B, Z), James Henderson Baird (Z., C), Thomas Barbour (B Z), Hugh Barr (Z, P, C), George Duncan Morrison Beaton (Z, C), George Beattie (B.), Robert Daniels Bell, M A (B, P) John Charles Bosworth (Z), Thomas Fraser Bowie (C), Forrest Brechin (B, P), Charles Brown (B), Charles Burns (B, P), George Yuille Caldwell (P), Donald [illegible]

[illegible] Grier (Z, C) Charles Francis Dyer Hammond (B), James Duncan Hart (Z, C) Frank Hauxwell (Z, C), James Waugh Hay (P, C), Robert M Cowan Hill (B, Z), Lawrence Hislop (P), [illegible]

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M B) and Bachelor of Surgery (Ch B) in the subjects indicated (A, Anatomy; P, Physiology; and M, Materia Medica and Therapeutics).—

Robert Adam (A., P), William Kirkpatrick Anderson (A., M), John William Arthur (A., P), Robert James Arthur (A., P, M), Thomas Ballantyne (A.) Andrew Farm Bell (A., P), Thomas Bennett, M A. (A, P), Archibald Grainger Bisset (M), Alexander Blair (P, M), William Thomas Bolton (A., P, M), James Campbell Bringan (P, M.), John Brown (M), Robert Bruce (A, P) John Miller Hopkins Caldwell (P), Angus Campbell (A, P), Robert Harold Campbell (P), Robert Pirploe Cartwright (P), John Cairns Christie (A), Alexander Erskine Clark (A., P, M), David William Davidson (A., P) Hugh Collin Davies (P), James Dick, M.A. (A) Mitchell Innes Dick (A P, M), William Dick (A) David Dickie (A., P), Hugh M Millan Donaldson (P) George Horn Downie (P), David Garfield Dykes (A, P, M), James Eadie (A, P, M), Cunison Charles Finlator (A., P, M), Eric Dalrymple Gairdner (A., P), George Garry (P) William White George (A), George Gordon (M), William Harvey (A P), James Thompson Kelly (P), John Muir Kelly (P, M), Alexander Dingwall Kennedy (P), Robert Dallas Kennedy (M.), John Kerr (P), Robert Laurie (A., P, M) Alexander Leggat (M) Archibald Leitch (M), William Jamieson Logie (A), Thomas Walter Love (A, P) Donald MacAulay (M), James Duff M'Culloch (A., P, M.), Alexander Armstrong MacFarlane (M), David Duncan Fraser Macintyre (M), John Matheson MacKellar (A., P, M.) Ivy M Kenzie, M.A (M), Alexander Stewart M'Millan (A, P, M), James Roy M Vail (M), James Anthony Maevea (A, P, M) Andrew Alexander M'Whan (A., M) William Main (P), Alexander Matheson, M A. (A., P) Peter Millar (P, M), Alexander John Mitchell (P), Spencer Mort (A P, M) Gavin Muir (P, M), Alexander Harper Napier (P, M), David Penman (A., P), Alexander M Millan Pollock (A, P) William Rankin, M A. (A., P, M), Daniel Falconer Riddell, M A (A, P, M), Peter Hamilton Robertson (A., P), Robert Clemens James Schlomka (A.), Frank Donald Scott (A., P), William Garrow Shand (A., P, M) Lawrence Drew Shaw (M), John Black Stevenson (A P) Wm David Henderson Stevenson, M A. (A P), John Barbour Stewart (A.), William Stewart (A, P), Arthur William Sutherland, M A. (A, P, M), John Wilson Sutherland (A., P, M) Peter Lindsay Sutherland (A, P), Joseph Walker, M A (A., P), Hugh Fleming Warwick (A.), William Norman West Watson (A, P), Robert Tait Wells M A. (M) John Forrest Weston (A., P), Joseph White, M.A, B Sc. (M) Griffith John Williams (A, P), James Wilson (A, P, M), Elored Wright (P) Hugh Young (A., P), John Young, Glasgow (A., P), and Watson Young (M) Women—Jeanie Auld (P.), Annie M'Caig Black (P, M), Agnes Wallace Cameron (P.), Mary Charlotte Cameron (A., P.), Ethel Lily Chapman (P.), Jessie Galloway Duncan (A., P.), Jane Reid Foulds Gilmour (A., P.), Margaret Hardy (A., P.), Alice Wesley Maclean (P.), Mary Lauchline M'Neill (A., P.), Anna Pollock Martin (P., M.), Eliza Jane Miller (A., P.), Isabel Deane Mitchell (A., P.), Charlotte Reid Park (P.), Ethel Jane Mildred Pryce (P.), Margaret Hossack Smart (A., P.), Jessie Marie Stewart (A., P.), Elizabeth Taylor Talbert (A., P.), Janet Gardner Waddell (A., P.)

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., Pathology; and M., Medical Jurisprudence and Public Health):—

William Armitage (M.), Alexander Grey Banks (P., M.), Robert Bryson (M.), George Frederick Buchan (P., M.), John James Young Campbell (P., M.), Alexander Adam Carruthers (P.), Walter Bartlett Chapman (P., M.), Ernest Hamilton Cramb (P., M.), Hugh William Crawford (P., M.), Alexander Dick (P., M.), Donald Douglas, M.A. (P.), Andrew Robertson Dow (P., M.), William Dow (P.), John Ferguson, M.A. (P., M.), Thomas Forsyth (P., M.), John Andrew Garden (P., M.), John Ritchie Gilmour (M.), John Miller Gordon (P., M.), John Guthrie (P., M.), John Andrew Hagerty (P.), Ronald Dingwall Hodge (P., M.), John Brown Dalzell Hunter (P., M.), Ernest David Jackson (P., M.), George Rutherford Jeffrey (P., M.), William Fletcher Kay (P., M.), John Kennedy (M.), Andrew Miller Kerr (P., M.), Stanley Everard Lewis (P., M.), Joseph Paterson Lusk (M.) Daniel Douglas M'Dougall, M.A. (P.), Alexander Macintyre (P., M.) John Chancellor M'Kenzie (P., M.), Thomas M'Laren (P., M.) Alexander Maclean (M.), John Maclean (P., M.) Dugald Henry MacPhail (P., M.), Richard Makins (P., M.), Robert Harry Manson (M.), Harry Somerville Martyn, M.A. (P.), Robert Menzies (P.), James Grant Millar (P., M.), Wm. Alexander Milne (P., M.) John Muir (P., M.), James Stuart Nicolson (P., M.), Robert Orr (P.), Thomas Rankine (P., M.), John Mark Reid (P.), Thomas Richmond (P., M.), David Riddell (P., M.), William Robertson (Blackwood) (P., M.), Norman Cumming Rogers (P.), James Russell (M.), Malcolm Bernard Gathorne Sionette (P., M.), John Williamson Smith (P., M.), Robert Cassels Smith (P., M.), David Spence (P., M.), John Stevenson (P., M.), Robert Rennie Swan (P., M.), William Wagner Turner (P., M.), John Unsworth (P., M.), Thomas Irby Wallace (P., M.), Alexander Brown Watt (P., M.), Peter Millar Waugh (P., M.), David Ashley Wilson (P., M.), and John Wilson (M.) Women—Helen Stephen Baird, B.A. (P.), and Jessie Seath MacEwen (P., M.).

At the recent professional examination for the degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

FIRST EXAMINATION.

Botany and Zoology.—Robert B. Carslaw, M.A.
Zoology and Physics.—John Taylor.
Zoology and Chemistry.—James H. Baird and Thomas Thom.
Zoology.—Walter G. Macdonald, M.A., Norman H. W. Maclaren, Matthew T. D. M'Murrich, Arthur Robertson, John M. Ross, Alexander C. Russell, and Joseph R. Sutherland.
Physics.—Elizabeth M. M'Vail.
Chemistry.—Frank Hauxwell, William L. Kirkwood, Morrison W. Smith, William Y. Turner, and George Young.

SECOND EXAMINATION.

Anatomy and Physiology.—Alexander Matheson, M.A., and William D. H. Stevenson, M.A.
Anatomy and Materia Medica and Therapeutics.—James Eadie, Spencer Mort, and William G. Shand.
Physiology and Materia Medica and Therapeutics.—John W. Sutherland.
Anatomy.—Joseph Walker, M.A.
Physiology.—Robert J. Arthur and Peter L. Sutherland.
Materia Medica and Therapeutics.—Alexander Blair, Cunison C. Finlator, and Daniel F. Riddell, M.A.

THIRD EXAMINATION.

Pathology.—John A. Garden, Ernest D. Jackson, and Andrew M. Kerr.
Medical Jurisprudence and Public Health.—George F. Buchan, William W. Turner, and Peter M. Waugh.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. von Herff of Halle has been appointed to the chair of Midwifery and Gynæcology.—*Berlin:* Dr. Brandenburg and Dr. Burghart have been recognised as *privat-docenten* of Internal Medicine.—*Cracow:* Dr. Maziarski has been recognised as *privat-docent* of Histology.—*Heidelberg:* Dr. Braus, prosector in the Anatomical Institute, has been appointed Extraordinary Professor.—*Leipsic:* Dr. Franz Windscheid, Director of the Policlinic for Nervous Diseases, has been appointed Extraordinary Professor. Similar promotion has been accorded to Dr. Kollman, *privat-docent* of Dermatology. Dr. Saxer has been appointed prosector.—*Munich:* Dr. A. Jesionek has been recognised as *privat-docent* in Dermatology.—*Rostock:* Dr. Korner has been appointed Ordinary Professor of Otology and Laryngology.—*Valladolid:* Dr. Quintero of Zaragosa has been appointed to the chair of Surgical Pathology.—*Wurzburg:* Dr. Overton of Zürich has been appointed Extraordinary Professor of Physiology in place of Dr. Schenck who goes to Marburg.—*Zurich:* Dr. Martin has been appointed to the newly-created Extraordinary Professorship of Anthropology.

MEDICAL MAYOR. Mr. Ralph Gooding, M.D. Lond., M.R.C.S. Eng., the mayor of Greenwich, has been presented with a chain and badge of gold.

MEDICAL MAGISTRATE.—Mr. Josiah Court, L.R.C.P. Lond., M.R.C.S. Eng., of Staveley, Chesterfield, has been appointed a justice of the peace for the county of Derby.

INFANT LIFE PROTECTION ACT.—At Plymouth on March 29th a woman was summoned for having failed to give notice to the coroner of the death of an infant of whom she had the charge. The evidence showed that the child died on March 6th and a certificate of the cause of death was given by a medical man who saw the child on the previous day, death being due to diarrhœa. The defendant pleaded ignorance of the Act, but the magistrates held that it was a serious offence and she was fined 11*s.*

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL: WINTER SESSION 1900-1.—The following prizes have been awarded:—First Year's Students: L. E. O. Norbury, the William Tite scholarship, £27 10*s.*; D. K. Coutts, College prize, £20; and R. J. H. Cox, College prize, £10. Second Year's Students: H. A. Kisch, the Musgrove scholarship, £38 10*s.*; E. W. Parry, College prize, £20; and T. P. Puddicombe, College prize, £10. Fifth Year's Students: C. N. Sears (Medicine), prize, £10; C. Burrows (Surgery, including Ophthalmology), prize, £10; R. E. Roberts (Midwifery and Diseases of Women), prize, £10; W. M. G. Glanville (Pathology), the Hadden prize, £10; C. N. Sears (Pharmacology and Therapeutics), prize, £10; H. W. Sinclair (Forensic Medicine and Insanity), prize, £10; H. W. Sinclair (Public Health), prize, £10. The Wainwright prize, £10, has been awarded to W. M. G. Glanville, B.A., of Christ Church, Oxford.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the winter session:—Descriptive Anatomy: Junior—I. Allaun, first prize (£3) and medal, and R. Bury, second prize (£1) and certificate; senior—J. Parker, first prize (£3) and medal, and Miss J. O. Hargrave, second prize (£1) and certificate. Practical Anatomy: First year—E. J. Clarke, first prize (£3) and medal, and R. Bury, second prize (£1) and certificate; second year—J. J. Connolly, first prize (£3) and medal, and J. S. Sheill, second prize (£1) and certificate; third year—E. C. Byrne, first prize (£3) and medal, and J. M. Moriarty, second prize (£1) and certificate. Practice of Medicine: C. W. Ewing, first prize (£3) and medal, and W. R. Ormsby, second prize (£1) and certificate. Surgery: A. Charles, first prize (£3) and medal, and W. R. Burkitt and J. P. Ziervogel (equal), second prize (cheque) and certificate. Midwifery: C. W. Ewing, first prize (£3) and medal, and Miss H. A. Hall and R. W. Burkitt (equal), second prize (cheque) and certificate. Physiology: J. J. Connolly, first prize (£3) and medal, and F. O'D. Fawcett, second prize (£1) and certificate. Chemistry: J. M'Quillan, first prize (£3) and medal, and L. A. Andrews, second prize (£1) and certificate. Pathology: A. Charles and T. A. Dillon (equal), first prize (cheque) and medal, and Miss H. A. Hall, second prize (£1) and certificate. Physics: M. B. Talbot-Crosbie, first prize (£3) and medal, and J. M. Hayes, second prize (£1) and certificate. The Schools of Surgery of the College will resume work after the Easter recess on Monday, April 15th.

PREVENTION OF CONSUMPTION.—The Marquis of Zetland presided on March 27th at a meeting of the York Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis which was held, by the permission of the Lord Mayor, in the state-room at the Mansion House, York, when it was unanimously resolved, on the motion of Mr. E. R. Turton, J.P., seconded by Mr. Philip Saltmarshe, J.P., to institute a sanatorium for the treatment of suitable cases of consumption upon a site which had been favourably reported upon. On the motion of the Rev. F. Lawrence, honorary secretary of the Church Sanitary Association, the following resolution was adopted: "In the opinion of this meeting it is desirable that preachers, teachers, and all persons who have the opportunity should inculcate the Christian obligation incumbent upon all, of endeavouring to secure for all pure air, pure water, abundant light, proper food and drink, wholesome surroundings, and the greatest possible immunity from infectious disease"—A public meeting was held at Trowbridge on April 3rd, under the presidency of the rector (the Rev D. Ryder), in support of the movement for erecting a sanatorium at Winsley for tuberculous patients of the poorer class from the counties of Gloucester, Somerset, and Wilts Dr. Shingleton Smith and Dr. Lionel Weatherly delivered interesting addresses. Dr. Weatherly, the chairman of the executive committee, stated that as a result of negotiations the Home Secretary had informed the committee that provided the money wherewith to erect the sanatorium was subscribed he would advise the King that his consent be given to call the institution the Royal Victoria Memorial Sanatorium for the three counties of Somerset, Gloucester, and Wilts The announcement was received with great applause The committee are hopeful that the money will be fully subscribed during the summer and the foundation stone laid There has been some opposition to the scheme for the erection of this sanatorium on the ground that it would be injurious to the neighbouring residents. This feeling is now fortunately at an end, and Mrs Lee, one of the objectors, has given £500 towards the sanatorium. The High Sheriff of Wiltshire (Mr. C Awdry) has promised £250, and there are several promises of £200 and many smaller sums.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Death Certification.

WHEN the House of Commons meets after the Easter recess Lord Hugh Cecil will address a question to the Home Secretary with regard to a certain death certificate in regard to which there has been an allegation of irregularity, and ask him whether he is prepared to take steps, either in regard to this particular certificate or generally, to safeguard the accuracy of certificates of death.

Accidents with Petroleum.

The private Members' Bill for raising the statutory flash-point of petroleum has been introduced again, but there is little prospect of its being discussed and almost none of its being passed Obviously this and the other subjects connected with the late inquiry by the Select Committee will have to be dealt with, if dealt with at all, on the responsibility of the Government.

Medical Officers of Health.

There has been introduced into the House of Commons a Bill "to amend the law relating to the qualification and tenure of office of medical officers of health, inspectors of nuisances, and sanitary inspectors and to provide for superannuation allowances to such officers and inspectors and for contribution towards such allowances by such [illegible] and to make other relative provisions." The [illegible] Francis Powell and among those [illegible] Sir Walter Foster, and Dr. Farquharson.

HOUSE OF COMMONS

TUESDAY, APRIL 2ND.

[illegible] Government [illegible] 16 years, a [illegible] now taking place at Leicester, and whether, since the vaccination officer had received no instructions to prosecute from the board of guardians, this officer was acting under direct instructions from the Local Government Board; if so, would he say under what authority the Local Government [illegible] of their inspectors, have reminded the vaccination officer of his duty in [illegible] the [illegible] officer [illegible] are [illegible]

Public Baths Closed on Sunday

Mr J F X O'BRIEN asked the Lord Advocate whether he was aware that Port Glasgow Town Council had decided to close the public baths [illegible] authority to cause the baths to be opened for a reasonable time every Sunday morning.—The LORD ADVOCATE replied: I am informed by the Local Government Board for Scotland that there has not been a single [illegible]

Appointments.

Successful applicants for [illegible] Institutions, and others possessing [illegible] are invited to forward [illegible] the Sub-Editor, not later than [illegible] of each week, for publication in the next number.

ADAMS, A. J. BOWMAN, M.R.C.S., L.R.C.P., has been appointed Medical Officer, the Barnes District of the Richmond Union and of the Children's Home Barnes, also Divisional Surgeon, Metro- [illegible]

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon. Salary £75 per annum, with board, residence, &c.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon. Salary £120 per year and £30 per year for dispensing, with furnished apartments and attendance.

Births, Marriages, and Deaths.

BIRTHS.

GALLOWAY.—On April 6th, at Harley-street, W., the wife of James Galloway, M.D., F.R.C.P., of a daughter.

MANNING.—On April 5th, at Hoddesdon, Herts, the wife of Thomas Davys Manning, M.B., B.S., of a son (Roger Davys).

POOLE.—On April 6th, at Hemplow, South Teddington, Hampton Wick, the wife of J. Copeland Poole, M.R.C.S., L.R.C.P., of a son.

MARRIAGE.

RAYNER—TAYLOR.—On April 2nd, at St. Marylebone parish church, Surgeon-Major Hugh Rayner, Royal Horse Guards, to Eva, younger daughter of John H. Taylor, of Devonshire place, W.

DEATHS.

DURRANT.—On April 6th, at Northgate-street, Ipswich, Christopher Mercer Durrant, M.D., F.R.C.P., and J.P. for the county of Suffolk, in his 87th year.

SYKES.—On April 1st, at his residence in Doncaster, John Sykes, M.D. Edin., F.R.C.P. Lond., J.P., aged 84 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MYSTERY AND MARRIAGE.

A MEDICAL correspondent forwards to us a mysterious circular which was recently sent to him as he thinks it might be of interest to us. The circular is printed in three languages—namely, German, French, and English. The English portion runs as follows:—

> "Since it may be that this circular could render any great service to any person, I publish it in that way.
>
> "A very rich count and of high position, 40 years old, looks by special motife, a [illegible] wife, strangers prefer [illegible]
>
> "He obliges [illegible] ake a considerable donation for the nomination. My name secures the greatest discretion in this earnst matter"

The "principal condition" is, it will be observed, left out; however, an inclosed slip informs us that further details can be obtained from a ship captain giving an address in Trieste All sorts of explanations might be given of the omitted passage as to the wife. The German version says simply "she must." Possibly the very rich count is like the prince in so many folk tales—generally compelled to go about in the shape of a boar or a serpent or some other unpleasant animal and wishes to be certain that his wife should be a lady of equable mind, or, like the gnome in Mr W S Gilbert's story, his beauty and stature may depend upon his not washing There is, however, a slip of green paper which perhaps explains matters On this are printed three lines as follows:

In der Hoffnung (auf Kind)
En ceinte dun enfant
Interesting state (w child)

We presume the very rich count wants an heir, if not from his own loins, then from those of someone else

HOLLANDS AND COCOA IN GOUT.

To the Editors of THE LANCET

SIRS,—Can any of your readers inform a medical colleague if they have found the use of hollands of benefit in modified gout of the extremities, fingers, and wrists, and whether cocoa is injurious in the gouty diathesis? I have been in the habit latterly of taking a cup of cocoa the last thing at night and suffer from pain and stiffness of the finger-joints, especially in the morning I have entirely given up wines or spirits, only taking a glass of light bitter ale with my dinner I understand at Carlsbad beer is permitted in moderation

I am, Sirs, yours faithfully,
April 4th, 1901 EXPERIENTIA DOCET

THE SALT CURE

To the Editors of THE LANCET

SIRS,—In a recent number of the *Contemporary Review* appears an article headed "The Salt Cure" and signed by Claire de Pratz. It describes in a popular manner the treatment of neurasthenia by means of the daily hypodermic injection of a few grammes of solution of neutral salts The tonic effects are said to be very remarkable. Dr. Jules Oberon, Dr Maurice de Fleury, and Dr Albert Robin are the authorities quoted Can you or any of your readers give me any information about this system? Has it been tried in England?

I am, Sirs, yours faithfully,
March 30th, 1901. S W.

MEDICAL FEES AT CORONERS' INQUESTS

To the Editors of THE LANCET

SIRS,—Can you inform me whether it is the custom to pay a medical man two guineas only when an inquest has been adjourned until a post-mortem examination has been made? I recently had to attend an inquest, make a post mortem examination, and attend again on another day at the adjourned inquest. I expected to be paid three guineas, but the coroner said he could only pay two, no matter how often the inquest might be adjourned

I am, Sirs, yours faithfully,
New Seaham, co. Durham, April 3rd, 1901 E. J HOWLEY.

*** It is generally maintained that there is not, and cannot be under the Coroners Act, any fee for attending an adjourned inquest. The question seldom arises, the medical man being, as a rule, only required to attend once We have already dealt with the subject very fully in two leading articles—one on Nov 3rd, 1900, p. 1285, and the other on Nov 24th, 1900, p 1511. In the second of these it was mentioned that Dr John Clark of Cleator Moor, Cumberland, after attending an adjourned inquest was unable to obtain more than two guineas from the coroner, but he subsequently succeeded in getting an extra guinea on applying to the county council In a second case of attendance at an adjourned inquest Dr Clark again claimed an extra fee from the county council, but this time without success. He thereupon applied to the Home Office, and after the lapse of a few months he received from the coroner a cheque for one guinea. In THE LANCET of Dec. 1st, 1900, p. 1613, we published a letter on the subject from the author of "A Brief Abstract of the Laws particularly Applicable to the Medical Profession" in Messrs Burroughs and Wellcome's Medical Diary. This gentleman quoted the following from Section 22 of the Coroners Act, 1887: "A legally qualified medical practitioner . shall be entitled to receive such remuneration as follows, that is to say, (*a*) for attending to give evidence at any inquest whereat no post mortem examination has been made by such practitioner, one guinea; and (*b*) for making a post-mortem examination of the body of the deceased, with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, two guineas." From this he argues that if it had been intended that no more than two guineas should ever become payable the two subsections would have had the word "or" between them and not the word "and" Moreover, he says, it cannot be argued that the evidence which the medical man would give under subsection (*b*) is covered by subsection (*a*)—ED L.

"THE PRINCE CHRISTIAN VICTOR MEMORIAL."

THE following further sums, amongst others, have been received by the honorary secretaries of the Prince Christian Victor Memorial Fund (Office, Horse Guards, Whitehall S W):—£10 10*s* each, Mr T Mark Hovell, Sir E H Sieveking and Sir Thomas Smith, Bart., £10, Sir Thomas Barlow; £5 5*s*, Mr H W Allingham, £5, Sir W H Broadbent, Bart., Mr G Anderson Critchett, and Dr T J Maclagan.

MEDICAL MEN AND HOSPITAL BOARDS

To the Editors of THE LANCET.

SIRS,—I feel like an old hen picking up crumbs in a yard, yet there are such valuable crumbs in THE LANCET that one often gets a good picking If the profession would follow THE LANCET and the *British Medical Journal* as organs of its central government the result, I am sure, would be admirable. I read that Sir J Crichton Browne repudiates the statement that medical influence on a board would convert a hospital into a mere scientific laboratory But why should not a hospital, or any other place attend [illegible] laboratory? The medical professic [illegible] for the welfare and comfort of all [illegible] for meritorious ends

I am, Sirs, yours faithfully,
Kew, Surrey, March 31st, 1901 JOHN A. HOME.

A QUESTION OF FEES

To the Editors of THE LANCET.

SIRS,—Would you kindly inform me as to the following question of fees? Last year I examined some volunteers for the army and at Christmas sent the account in to the officer commanding for 5*s* each man. He has kindly sent me 2*s* 6*d*. for each and informs me that that is the amount allowed by the battalion. I took that amount off my bill and returned it showing the balance due to me Did I do right? Hoping the answer may be of service to other medical men,

I am, Sirs, yours faithfully,
SUBSCRIBER.

*** We understand that the commanding officer has no discretion to increase the fee—ED L.

A WARNING TO PUBLIC VACCINATORS.

To the Editors of THE LANCET

SIRS,—We public vaccinators are a patient race, yet we have had that imposed upon us which might indeed a saint provoke We are now required to write all our notices in duplicate, and books with alternate thick and thin pages with an accompanying page of carbon paper are supplied as a means to that desired end. So I obediently (as is my wont) set myself to work, and whilst so engaged was called away to see a patient. Instead of being attended to by that gravity that I expected and which my words merited I was distressed by an almost unbecoming exhibition of merriment on the face of my patient. I cast about to solve this incongruous and unexpected overflow of spirits. I had not far to seek. My hands were as black as if I had been cleaning a grate and my nose and eyes, which had been itching whilst bent over this vile carbon paper, were of the same tint as my hands. The lines of Goldsmith—

"The swain mistrustless of his smutted face
While secret laughter tittered round the place"—

were, indeed, too applicable to myself Let this letter be a warning to others to bear in mind the unexpected results of this carbon tissue lest they also become a cause of merriment in others.

I am, Sirs, yours faithfully,
April 6th, 1901. P V.

"ELECTRICALLY LIGHTED BRUNTON'S AURISCOPE."

To the Editors of THE LANCET.

SIRS,—Referring to Messrs John Weiss and Son's letter in THE LANCET of March 30th, p. 933, I have seen the figures of the instrument they mention in their catalogue. Anyone must see, however, at a glance that my auriscope differs very materially from theirs, thus—1. My instrument is adjustable to the trumpet of any Brunton's auriscope. 2. The trumpet of the auriscope does not require to be made removeable to admit of my electric lamp being fixed in position 3 The apparatus can be used with any battery not too strong for the lamp, but—and this is one of my great points—it is specially adapted to the cheap dry-cell batteries now sold which cost only 2*s* 6*d*.

each. 4. The electric lamps are also very cheap and can be screwed into position should a new one be required by two or three turns 5. The wires connecting the auriscope to the battery are fixed instantly The terminals, moreover, are so arranged that the battery cannot possibly run down when not in use. 6 My electric lamp can be used for either the auriscope or the holder that is sold with the battery. All, therefore, that is needed for my auriscope after first purchase of the instrument and battery is the renewal of the dry cell at a cost of only 2s. 6*d* and after long periods a new lamp also at a small cost. I am, Sirs, yours faithfully,

GEORGE H. VOS, M.B. Cantab.

Tottenham, N , April 3rd, 1901.

"PLACE OF RESIDENCE FOR A RETIRED SURGEON."

To the Editors of THE LANCET.

SIRS,—May I through your columns thank "F. H. A." for his kind advice in THE LANCET of April 6th, p 1056, and at the same time ask, are not Bournemouth, Branksome, and the neighbourhood very hot and relaxing in summer, especially after the keen cold of the eastern counties? I am, Sirs, yours faithfully,

April 8th, 1901. P. P.

THE TEMPERANCE QUESTION.

To the Editors of THE LANCET.

SIRS,—Would you or any of your readers kindly let me know of the latest and most reliable work on the temperance question from a medical point of view—whether moderation or total abstinence is the most healthy system? I am, Sirs, yours faithfully,

March 29th, 1901. APRIL.

⁂ Among publications written from the total abstinence point of view mention may be made of several brought out by Sir Benjamin Ward Richardson, such as "Brief Notes for Temperance Teachers," "Alcohol: Its Action and its Use" (Six Cantor Lectures delivered before the Society of Arts), "Moderate Drinking: For and Against" (a lecture delivered in Exeter Hall), "Results of Researches on Alcohol" (an address delivered at Oxford), "The Action of Alcohol on the Mind" (an address delivered at Cambridge) These five appeared between 1874 and 1883 Some of them may be obtained from the Church of England Temperance Society, 4, The Sanctuary, Westminster. Dr. Norman Kerr was also the author of several works of the same kind, including "The Action of Alcoholic Liquors on Health," 1876 "Wines," 1882, "The Truth about Alcohol," 1885. See also "L'Alcool et L'Alcoolisme," by Dr. Triboulet and Dr. Mathieu (Paris: G. Carré et C. Naud), reviewed in THE LANCET of Jan 19th, 1901.—ED L

A WARNING.

To the Editors of THE LANCET.

SIRS,—I think it well to warn my fellow practitioners about a person who called on me recently. She was a tall, dark, lady-like woman and said that she was a "Red Cross" nurse of 19 years' standing She was anxious to find accommodation in the house of a medical man for her brother, Captain Stanley, who had been severely wounded in South Africa, having had six bullets in him, four of which had been removed, while the remaining two (in his lungs) Mr. Treves was going to try to relieve him of. She herself was all through the siege of Ladysmith, and as she was returning to South Africa on Wednesday, April 10th, she was most anxious to arrange matters for her brother before leaving England. The brother, she said, was at present on board ship waiting to be removed to a nursing home, or preferably to the private house of a medical man. Whilst calling at the Herbert Hospital, where she was well known, she happened to meet a Dr Bateman of Blackheath, who told her that he thought that I took in resident patients. Hence her visit. Money was no object.

I told my visitor that there was no one called "Dr. Bateman" at Blackheath and showed her that there were no such name and address in the Medical Directory. But she reiterated the statement. As to references, there were plenty and good ones, even Lord Roberts himself, who was much interested about her brother's case On her return she said that she would "ring up" Sir William MacCormac and that he would at once write to me about the matter. Moreover, the money would be paid in advance. Also she had been dining with Lord and Lady Dundonald a few days ago, whose entry into Ladysmith she should never forget Previously to coming to me she said that she had met a nurse from Guy's Hospital who showed her the way to my house I have since found out that she told a very similar story to this nurse, who has charge of one of my patients, with this addition—that unfortunately she had come away without her purse, but that if she could be assisted the amount would be promptly returned. I am glad to say that the nurse was not caught. This caution may be of service to some of your readers

I am, Sirs, yours faithfully,

April 8th F. G LARKIN.

UNPLEASANT ENTERPRISE

WE have received from a correspondent a letter sent to him by the Law Accident Insurance Society, which society sent him at the same time a reprint of a paragraph from the *Yorkshire Evening Post* and a form to fill up for the insurance by an employer of his employés. The cutting refers to the death of certain children owing to the mistake of a dispenser. We think it rather hard that this man's case, with his full name and the fact of his arrest, should be circulated as an advertisement by the Law Accident Insurance Society. He is under remand, and his serious trouble, whether he brought it upon himself by careless conduct or no, should be respected. Nor do we see how any premium paid by an employer would ever protect a dispenser from a charge of manslaughter if he made a fatal mistake in dispensing. We agree with our correspondent that the enterprise of the Law Accident Insurance Society is in this case unfavourably displayed.

◆

Nemo.—We are not quite certain what it is that our correspondent objects to, for he does not draw our attention to any particular point in the advertisement. There can be no strict rule about the propriety of writing books addressed to the public or about advertising those books in the lay press If a book gives, or is intended to give, useful information to the public and does not invite the public directly or indirectly to consult the author or any particular medical man, more latitude can be allowed in the matter of advertisements. Because a medical man may not appeal to the public in his professional character it does not follow that he must cut himself off entirely from the public.

Rob.—1. "The A.B C. of the X Rays," by W. H. Meadowcroft. London: Simpkin, Marshall, Hamilton, Kent, and Co Price 4s 2. "The Roentgen Rays in Medical Work," by David Walsh, M.D. Edin. London: Baillière, Tindall, and Cox. The former of these books is a very simple popular work. The latter is a useful account of the application of the rays to medical work.

G. P.—It may be very dangerous to prescribe for a patient on the statement of his wife If the diagnosis of the case was originally made by the medical man he might trust to the patient's wife, if she seemed a sensible woman, for a report upon symptoms, but he certainly should not revise his course of treatment without seeing the patient.

A. G C.—An account of Marochetti's observations appeared in the *Westminster Review* for 1824 and in Abhandl. über die Wasserscheu (1843). So far as we know nothing more is known of the treatment

Halifax.—We cannot advise our correspondent to write in a lay paper upon a matter the interest of which is purely medical. Such a proceeding would certainly be unprofessional.

Lactic Acid.—We do not think the public dissemination of the testimonial advisable There is no evidence that the medical man in question has authorised the circular.

Mr. N. A. Butterfield.—"Diseases of the Lungs," by J. K. Fowler, M D., F.R C.P., and R. J. Godlee, F.R.C.S, (Longmans and Co, London), price 25s.

ERRATUM.—In the letter in our correspondence columns, headed "The Case of an Election," THE LANCET, April 6th, p. 1044, second line, "at the above hospital," should read, *at the Samaritan (Free) Hospital for Women and Children*.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423 Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mr. B. G. Advani, Lond.; Messrs. Armour and Co., Lond.; Mr. C. E. Addison, Colchester; Dr. T. C. Allbutt, Cambridge; A. J. M.

B.—Mr. W. M. Beaumont, Bath; Mr. H. Butterfield, Northampton; Dr. G. S. Barksdale, Fern Bank, U.S.A.; Mr. P. Benham, Lond.; Bedford County Hospital, Secretary of; Dr. Bellini, Athens; Mr. J. M. A Clinical Lecture

ON

CARCINOMATOUS STRICTURE OF THE DUODENUM.

Delivered at St. George's Hospital on March 11th, 1901,

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, ST. GEORGE'S HOSPITAL.

GENTLEMEN,—A plumber, aged 50 years, was admitted to the hospital on Nov. 29th, 1900, with weakness, anæmia, vomiting, and abdominal pain. His past history showed that he had been healthy until two years ago, when he began to suffer from pain in the epigastrium immediately after food; this pain had continued on and off since. In July and August, 1900, he was laid up with vomiting, and again on Nov. 8th. During the last year he had lost weight and had grown paler, and had suffered from constipation. He had had no previous illnesses, there was no reason to think that he had had syphilis, and he had taken beer moderately. The patient was big-boned, spare, and anæmic, and presented practically no objective signs of disease in the chest or abdomen. The tongue was moist and slightly furred, the teeth were bad, but there was no blue line on the gums. The lungs were normal, the heart was not enlarged, and the sounds, though distant and rather weak, were otherwise normal; the second sound was not accentuated either over the pulmonary or aortic areas Nothing abnormal could be felt in the abdomen, but the skin was dry and inelastic. There was no abnormal resistence in the abdomen and no distension; at times, indeed, in the course of the case the abdomen became retracted, while before bouts of vomiting it became rather fuller. No enlarged glands could be felt in any part of the body. The blood showed a secondary anæmia, the red corpuscles numbered 3 340,000, the hæmoglobin amounted to 70 per cent., and there was a slight leucocytosis. The urine varied in specific gravity, with the occurrence of vomiting, from 1010 to 1030, and sometimes contained a trace of albumin. Further changes in the urine will be referred to later. The pulse was normal in rate, rhythm, and tension. The vomited matters were found not to contain any free hydrochloric acid. On admission a tentative diagnosis of carcinoma of the pylorus was made although no tumour could be felt. After a few days the stomach increased in size and seemed to support this diagnosis. On the other hand, the man's work, that of a plumber, and the history that he often took his meals without being able to wash his hands suggested that the anæmia, debility, and gastro-intestinal disturbance might be due to lead poisoning. However, there was no lead line on the gums such as there would have been, since his teeth were bad, if lead had recently been introduced into the system. There was no wrist-drop or paralysis and the pain was not that of lead colic. It is well to remember that it is easy to overlook the presence of grave abdominal disease in cases of suspected plumbism; thus I remember performing a post-mortem examination on a worker in lead who had a blue line on his gums and had had vomiting, constipation, and abdominal pain; he had a twist in the small intestine near the ileo-cæcal valve, at a point where the ileum was bound down for the last five inches to the posterior abdominal wall by a congenital deficiency of the mesentery. Incidentally it may be mentioned what an anxious problem the diagnosis of acute intestinal obstruction is in a patient with tabes; gastric crises may closely imitate mechanical obstruction and yet, of course, tabes in no way protects against acute intestinal obstruction. One is conscious of the importance of making a correct diagnosis so as to avoid an unnecessary operation on the one hand, and the calamity of allowing a patient to die from unrelieved obstruction on the other. Some years ago a patient under my care with tabes had an unusually severe and prolonged gastric crisis, and these questions were solved by waiting for developments.

A third possibility as to the condition at work in our patient was that it was a case of oral sepsis and that he was suffering from septic gastritis due to micro-organisms and pus swallowed as the result of pyorrhœa alveolaris. He was, indeed, given Giesshübler water to wash his mouth and teeth with and was provided with a tooth-brush; this simple mineral water was recommended to me by Mr. H. L. Albert for its purifying and cleansing effect on the teeth. The fact that the patient's general aspect suggested malignant disease did not necessarily render it unlikely that the whole condition was one of gastritis due to pyorrhœa alveolaris, for cases in which an initial diagnosis of carcinoma of the stomach had been arrived at have been cured by removing the cause—pyorrhœa alveolaris (W. Hunter[1] and R. J. Godlee[2]).

Turning now to the progress of the case, the patient vomited occasionally after admission and on Dec. 6th brought up 11¼ pints in 15 hours; the vomit contained bile but no free acid Some of the vomit was dark in colour and extremely offensive; the presence of bile made it clear that the obstruction, if any existed, was below the level of the biliary papilla in the duodenum and it put the tentative diagnosis of carcinoma of the stomach out of court. After this copious vomiting the excretion of urine was suppressed. This is sometimes seen in cases of dilated stomach with copious vomiting and is analogous to the anuria that occurs in cholera. The stomach was washed out and the patient was put on rectal feeding. As the vomiting stopped he was, three days later, put back on to some food by the mouth, water being given by the bowel. On Dec. 10th the stomach was washed out. Two days later he vomited 78 ounces, having only had 30 ounces by the mouth since the stomach was washed out There was therefore considerable gastric secretion or gastro-succorrhœa. This may be correlated with the fact that the chlorides in the urine were frequently found to be almost absent After this rectal feeding was again resorted to for a time. On Dec 17th the urine (specific gravity 1012) was found to turn of a dark port wine to brown colour when heated with nitric or any other mineral acid. The darkening was extremely marked and attracted instant attention. This colouration is produced by two different substances in the urine, the commonest being a colourless chromogen which represents indol in the alimentary canal and indican in the urine The other body is melanin, the pigment found in melanotic sarcoma. Melanin is passed in the urine in cases of large secondary melanotic growths in the liver such as are generally secondary to a primary melanotic sarcoma of the uveal tract in the eye. Melanin is nearly always passed in a colourless or chromogen form (melanogen), and only appears after standing and oxidation or when nitric acid or some other agent, such as bichromate of potassium or a solution of perchloride of iron, is added to it. The colouration then occurs at once. The patient's urine did not darken with perchloride of iron, so the body was not melanin. It was therefore plain that there was some body allied to indican in the urine which was due to fermentation taking place in the intestinal tract and the absorption of bodies allied to indol. Auto intoxication of intestinal origin frequently shows itself in this way in the urine. The appearance of the urine was exactly the same as that figured by Mr. A. Pearce Gould[3] in a case in which death occurred from toxæmia following acute intestinal obstruction. Dr. G. A. Buckmaster, who devoted much time to examining the urine, prepared considerable quantities of indican from the urine and found that there was 1 6 per cent of creatinin in the urine, making the approximate weight passed in the 24 hours' urine 2 4 grammes as against the normal 0 9 gramme. What this increase in creatinin was due to or what it signifies is doubtful. It occurred to me that possibly it was due to creatin taken in from the suppositories on which the patient was subsisting, but Dr. Buckmaster's analysis of a suppository showed that it contained practically no creatin Creatinin in the urine is either due to creatin taken by the mouth or is derived from the metabolism of the muscles. As it was apparently not due to food, it must be assumed that it was derived from the muscles of the body. The amount of urinary creatinin is said to be increased in wasting diseases, and as the patient was certainly losing flesh this seems the most likely explanation. For a few days the patient rallied and he took food by the mouth, but on Dec. 21st he vomited four times, bringing up 58 ounces of bilious fluid, and rectal feeding was again employed. The next day hiccough began, and in spite of all kinds of varied remedies continued for a week, only stopping after intravenous transfusion (80 ounces) was performed by Dr. S. V. Pearson. After this the patient again improved for a time. On Jan. 7th, 1901, a rash appeared on the abdomen, and on the following day the amount of chromogen (indican) in the urine, which had for some time been small, was much increased, the urine, when warm, turning of a brown sherry colour with HNO_3. The interest of this rash is that in Mr. A. Pearce Gould's case of toxæmia after acute intestinal obstruction there was an urticarial eruption associated with this change in the urine. The patient began to wander, tried to get out of bed, passed his urine and fæces in bed, and was presumably suffering from auto-intoxication. On Jan. 10th he was again transfused and he showed some slight improvement. His temperature now began to go up and the left knee became swollen, Mr. Sheild opened the knee-joint and let out some thin pus which was found by Dr. C. Slater to contain streptococci. A few abscesses appeared in other parts of the body and it was clear that he had developed pyæmia. The probable source of infection was the transfusion wound which had been slow to heal. The treatment was directed against the streptococcal pyæmia by giving subcutaneous injections of anti-streptococcic serum. Sera from different sources were employed so as to hit off, if possible, a strain of streptococci the same as, or similar to, that causing the hæmic infection. The patient gradually got weaker, passed into a condition of semi-coma, and, as before, had attacks of vomiting from time to time; the severity of the pyæmia passed away and as far as that was concerned the treatment was successful, but the patient died from exhaustion on Feb. 6th.

[3] Transactions of the Clinical Society of London, vol. xxxi., p 47.

The urine, which throughout the course of the disease was diminished in amount, was constantly noted by Mr. A. S. Jex Blake. Its specific gravity was usually between 1010 and 1018; it was acid, sometimes it showed a trace of albumin, but never, even when suppuration was taking place, contained albumose. The amount of urea varied between 1·6 per cent. and 2·3 per cent., the normal being about 2 per cent. The indican reaction varied from time to time, sometimes being marked, at other times almost disappearing. The urine was free from urobilin; sometimes the chlorides were practically absent, while at other times they returned. The fæces contained bile and were often extremely offensive.

The case presented the features of recurrent attacks of vomiting, probably due to a dilated stomach, but as the vomit contained bile the obstruction was evidently lower down. The abdomen was never distended and was often much retracted, so it was assumed that there was obstruction in the small intestine, but as no tumour could be felt at any time the diagnosis was not thought to be sufficiently assured to justify an exploratory operation. It is noticeable that the bouts of vomiting followed the return to feeding by the mouth. That the obstruction was not absolute was shown by the passage of fæces containing bile.

At the necropsy, performed by Dr. W. J. Fenton, there was no ascites nor peritonitis. There was a tight stricture of the third part of the duodenum just where the mesentery crosses over it. From the outside it looked as if a string had been tightly tied round the duodenum; no growth could be seen externally. At first sight it looked like an example of stricture of the duodenum caused by pressure exerted by the superior mesenteric vessels and nerve. This condition has been described by Byrom Robinson[4] who performed laparotomy unsuccessfully on a case with enormous dilatation of the stomach and duodenum from this cause; he has also noted 20 cases in which dilatation of the duodenum began at this point and considers that it is especially apt to develop in patients with visceroptosis when lying on their backs. This is perhaps rather a novel view, but it deserves testing, and is at any rate on the same lines as the production of hydronephrosis by the pressure of abnormal renal arteries on the ureter.[5] Above the stricture the duodenum and stomach were slightly dilated and their muscular walls were a little hypertrophied. The small intestines and colon were collapsed. On opening the duodenum there was seen to be a white flat growth replacing the mucous membrane of the duodenum in the immediate neighbourhood of the stricture; there was more growth above the stricture than on the side towards the jejunum. The growth looked like a thick filter paper perforated at the apex fitted into a funnel. The stricture just admitted a cedar pencil. Above the stricture the growth tracked up towards the biliary papilla which it touched, and was just beginning to obstruct the outflow of bile since the common bile duct was dilated.

Microscopically the growth was a carcinoma with columnar cells. There were no secondary growths in any part of the body. The pancreas was large and fibrotic, probably from extension of infective catarrh from the duodenum into its ducts; Wirsung's duct was not dilated; there was no trace of growth in the pancreas. The mucosa of the stomach appeared healthy to the naked eye. Microscopically the cells of the glands were much altered and degenerated, but possibly there was a post-mortem change. The liver, which weighed four pounds, was in a condition of cloudy swelling; the gall-bladder was full of bile and the ducts were dilated. There was no jaundice and there never had been any during the patient's stay in the hospital. The other organs were healthy except for obsolete tubercle at the apices of the lungs.

There was, therefore, a carcinomatous stricture of the third part of the duodenum, which, though not entirely occluding the lumen of the bowel, had given rise to recurring attacks of obstruction. Liquid food in small quantities could have passed into the jejunum, but it is probable that from time to time food collected in the commencement of the third part of the duodenum just above the stricture and by bulging it downwards led to traction and so to complete closure of the fixed and already strictured part of the bowel.

As to treatment, rectal feeding was successful in temporarily alleviating the symptoms but could not be permanently persisted in, as the condition of the patient was far from being good. Gastro-enterostomy would no doubt have relieved him for a time—i.e., until he died from malignant disease—but the diagnosis was never sufficiently dogmatic to justify a speculative laparotomy in a man so gravely ill. It is true that stricture or growth in the small intestine was suspected on the grounds of the bilious vomiting, but in the absence of anything palpable on the abdomen this hardly justified an appeal to surgery.

General Remarks.

Malignant disease rarely attacks the small intestine, and when it does the growth is usually either in the duodenum or close to the ileo-cæcal valve. Malignant disease is less infrequent in the duodenum than in the lower part of the ileum, but is decidedly rare even there, as shown by the following statistics given by Schlesinger.[6] In 25 years there were in Vienna only seven cases of primary malignant disease of the duodenum among 42 000 post-mortem examinations, of which 3583 were cases of malignant disease, and of these 443 involved the intestines. In 18,000 necropsies at Guy's Hospital there were 10 cases of primary malignant disease of the duodenum, four of which were carcinoma (Perry and Shaw).

Malignant disease of the duodenum may be either carcinoma or more rarely sarcoma. Libman[7] has collected 15 cases of primary sarcoma of the duodenum. Some of the cases described as lympho-sarcoma, however, may have been only lymph-adenoma. A comparatively extensive tract of the duodenum may be involved by sarcoma. Its wall is usually softened by the sarcomatous growth and is often dilated, so that there are no symptoms of stenosis.

Primary carcinoma of the duodenum is much more localised and tends in most instances to produce an annular stricture. The cases in which it does not produce this effect are those where a small growth arising from the duodenal surface of the biliary papilla proves fatal by inducing jaundice and cholæmia or suppurative inflammation of the biliary tract before it has had time to grow to any size. There was an excellent example of this in the post-mortem room last week; a patient under the care of Dr. Isambard Owen, a man, aged 52 years, with jaundice and rigors, had a small columnar-celled carcinoma involving the duodenal surface of the biliary papilla and setting up suppuration throughout the bile-ducts and in the gall-bladder. With this general exception duodenal carcinoma gives rise to stricture of the intestine, at least in the great majority of cases. Schlesinger, Letulle,[8] and others have, however, recorded examples of exceptions to this general rule.

[8] Gazette des Hôpitaux, Dec. 9th, 1897.

Like carcinoma of other parts of the body, carcinoma of the duodenum is a disease of late middle or advanced life. In 41 cases which I have collected from various sources the average age was 52 years, being 53·4 years in 10 females and 51·7 years in 31 males. In 10 out of 33 cases collected by Nattan-Larrier[9] the patients were over 70 years of age. In the 41 cases which I have tabulated, probably including many of Nattan-Larrier's, seven patients were 70 years of age or upwards, the extremes being 80 years and 27 years. In 42 collected cases (not including the present case) 32 of the patients were males and 10 were females. The marked predominances of the male sex corresponds with the greater number of male victims in carcinoma of the tongue, œsophagus, stomach, and rectum. Malignant disease resembles ulcer of the duodenum in its preference for the male sex; in 127 cases of duodenal ulcer tabulated by Cullen[10] 108 were males and 19 were females.

Carcinoma of the duodenum is a columnar celled carcinoma which may show a transition to a spheroidal-celled type or can undergo colloid change. The growth almost always leads to stricture of the duodenum and to dilatation and hypertrophy of the proximal part of the duodenum and stomach. In a few instances the growth has perforated into the general peritoneal cavity and given rise to peritonitis; a localised abscess has also been observed from perforation. A definite tumour is palpable in the position of the duodenum in a small number of cases.

Carcinoma of the duodenum is difficult to recognise during life and presents a different clinical picture according as the growth is situated in the first, the second, or the third portion. It will therefore be most convenient to describe the three different forms.

1. *Carcinoma of the first part of the duodenum* is rare; in 40 collected cases the first part was affected alone in eight and together with the second part in five more. It is indeed remarkable that carcinoma of the pylorus does not extend into the duodenum more often than it does. It is, of course in some cases, where there is a growth on the position of the pylorus, difficult or impossible to be certain exactly how much or how little of the commencement of the duodenum has been involved, but most observers believe that carcinoma of the pylorus stops short at the pylorus. It is a point of some importance to have grounds for or against this belief, since if carcinoma of the pylorus does not tend to infiltrate the duodenum, excision of the pylorus for growth may, as far as this point is concerned, be recommended with a fair prospect of success. This question has recently been investigated by Cuneo and Lucène[11]; in 10 specimens removed during life for pyloric carcinoma, in only one did the growth manifestly extend into the duodenum and in three others there were microscopic foci of infection cells in the lymphatic vessels but not extending more than two centimetres from the pylorus; in the other six cases the duodenum was microscopically healthy. Therefore in cases where the pylorus appears to be healthy to the naked eye a surgeon should, in excising the pylorus for carcinoma, be fairly safe if he removed the first three centimetres of the duodenum at the same time. Carcinoma of the first part of the duodenum has practically the same clinical picture as carcinoma of the pyloric end of the stomach, and as it is a rare disease the commoner form will probably always be diagnosed in its place. It is, therefore, conveniently called "juxta-pyloric carcinoma of the duodenum"; another name for it, since it is above the level of the biliary papilla, is "supra-ampullary carcinoma." It is interesting to note that, just as in the case of the stomach, so in the first part of the duodenum, carcinoma may develop on a former ulcer. Perry and Shaw[12] give five cases in which a simple ulcer was thought to have become malignant. Nattan-Larrier refers to five additional cases of ulcer carcinomatosus of the duodenum, including one published by Letulle of colloid cancer in a man who had some years before been under his care with definite symptoms of duodenal ulcer. Ulcer can hardly be an important factor in the causation of duodenal carcinoma, since duodenal ulcer is practically limited to the first part of the duodenum, and carcinoma in that situation is rare. Thus 123 out of 149 duodenal ulcers collected by Dreschfeld[13] were in the first part of the duodenum. Again, from the frequency with which duodenal ulcer is latent during life, clinical evidence in favour of the previous existence of a simple ulcer is seldom forthcoming. It is, therefore, on the post-mortem observation that we have to depend, and it may be rather difficult to be sure whether there is wide ulceration and sloughing of a growth or the development of carcinoma in a pre-existing ulcer.

2. *Carcinoma of the second part of the duodenum*.—This is the most frequent form of primary carcinoma of the duodenum. In 40 collected cases the growth was limited to the second part in 24, while in five others the first part was invaded as well. If it occurs in the upper part of the second portion of the duodenum—that is, above the level of the biliary papilla—it will give rise to much the same symptoms as carcinoma of the pylorus; if, on the other hand, it involves the biliary papilla the flow of bile will be interfered with and jaundice or other complications will occur; while if it is well below the biliary papilla it will by narrowing the lumen give rise to obstruction with bilious vomiting. Carcinoma has a special tendency to arise in the duodenal mucous membrane covering the biliary papilla. This must be differentiated from carcinoma arising inside the biliary papilla or in the ampulla of Vater, the channel common to the terminations of the common bile-duct, and Wirsung's duct of the pancreas. The term "carcinoma of the ampulla of Vater" is sometimes erroneously applied to a carcinoma of the duodenum involving the biliary papilla. When carcinoma arises on the duodenal surface of the biliary papilla the flow of bile is interfered with, though it is not, as a rule, completely blocked. A change that very frequently follows on this and may rapidly kill the patient is suppurative inflammation of the bile ducts. The partial stagnation favours infection, and the growth, while not completely occluding the lumen of the papilla, favours duodenal catarrh and its extension into the common bile and pancreatic ducts. The duct of Wirsung may also become dilated. The biliary papilla is a favourite site for the development of carcinoma; possibly this is due to some fœtal displacement or irregular inclusion of epithelial cells during the development of the hepatic diverticula from the primitive duodenum. It is interesting to note that the disturbance, incident on the outgrowth of the hepatic diverticula from the duodenum, may lead to a congenital narrowing or to atresia of the bowel at this point, analogous to congenital atresia of the œsophagus. An innocent papilloma is sometimes seen to arise from the duodenal surface of the biliary papilla, and it is, I think, probable that carcinoma may subsequently develop in such a growth. The question has been raised whether impacted gall-stones inside the ampulla of Vater have any bearing on the development of new growth on the duodenal surface of the papilla. On the face of it this seems improbable, and though D. K. Dickinson[14] has recorded the association of these two conditions, this experience is almost unique.

From its situation primary carcinoma of the intestinal mucous membrane of the biliary papilla is spoken of as juxta- or peri ampullary carcinoma. As a rule, peri-ampullary duodenal carcinoma imitates carcinoma of the head of the pancreas and gives rise to jaundice associated with an enlarged gall-bladder. Jaundice was present in 23 out of 25 cases quoted by Mathieu.[15] In rare instances, however,[16] the growth, although involving the papilla or invading the bile duct, does not give rise to jaundice. The jaundice may vary, be intermittent, or, as in the case under the care of Dr Isambard Owen, disappear for a time; it thus differs from the permanent and progressive jaundice seen in carcinoma involving the common bile duct, the cavity of the ampulla Vateri, or the head of the pancreas. The intermittence or disappearance of jaundice in duodenal carcinoma involving the biliary papilla must depend on the growth ulcerating and thus no longer obstructing the flow of bile; if the tumour goes on growing it may again lead to obstructive jaundice. Though the biliary papilla is a favourite starting point for carcinoma the growth may begin elsewhere in the second part of the duodenum and involve it by extension.

3. *Carcinoma of the third part of the duodenum* is the least frequent of all the three varieties. In 40 collected cases (not including the present example) it was only found in three. It is sometimes spoken of as infra ampullary or juxta-jejunal carcinoma of the duodenum. The symptoms are those of intermittent obstruction, as in the case brought

forward to day, with bile in the vomit. It thus resembles pyloric obstruction except for the presence of bile and pancreatic juice in the vomit. The occurrence of bile should at once suggest carcinoma of the duodenum below the biliary papilla or a gastro-biliary fistula. In such a case the vomit should be tested for trypsin by seeing whether fibrin is digested in an alkaline solution. In this way the diagnosis between the two conditions might be made.

AUTOPSYCHORHYTHMIA OR REPETITION PSYCHO-NEUROSIS.

MORBID RHYTHMIC FORMS OF AUTOMATICITY AND RHYTHMIC FORMS OF MENTAL ALIENATION.

BY C. H. HUGHES, M.D.

THE pathetic story of the accountant who, in a state of nervous exhaustion and cerebrasthenia, was carried to Bethlem Hospital pitifully repeating, "Once one is two, once one is two," the mistaken calculation having ruined him, is well known in the literature of nerve perturbation. The record is a story of brain exhaustion often repeated in other forms, the real nature of which is often not well understood in time, either by the family medical adviser or the public, to avert disaster. There are other phases of this morbid mental state in which a fear of mathematical inaccuracy or mental agitation on account of the interrupted rhythm are not characteristic, but where simply an insistant impulse to automatic repetition exists that will not readily down at the bidding of the normal will, even though regard for the proprieties of environment demand suppression. The constant repetition of a rhythmical movement in the mind, regardless of time or place or circumstance, and which an enfeebled volition cannot regulate to conform to the requirements of environment, characterises this symptom of brain overstrain and psycho-motor automatic impulse. Neuropathic and consequent psycho-motor neurasthenia appear to be at the bottom of this condition, or have probably been at some time in the life of the nervous mechanism, before the inception of the morbid automatic repetitional impulse. It is as much a *symptom* as the ill-at-ease, restless, tired, and fidgety state and morbid phobias of neurasthenia are symptoms.

Tuke (Psychological Dictionary) touches this subject closely under the discussion of imperative ideas, coprolalia, and obsession, and mentions the instance of a friend who wrote to him after composing a poetical work, saying in his letter that he longed to get the poetical work out of his brain and to begin on "fresh woods and pastures new," but found it "difficult to make the vibrations cease when the intellectual chimes have been set to a particular tune," recognising the brain automaticity which is an essential feature of what we are attempting to describe. I would take this case from the class of imperative ideas and place it in the new psychological class like the following, to which I would apply the new term which I coin—"autopsychorhythmia."

A handsome, bright, and accomplished young lady, aged 18 years, with a maternal unstable nerve heritage but a healthy father, a student of music, advanced and promising, came to me from a distant city suffering from exaggerated reflexes, insomnia, hyperideation, troublesome illusional fancies, and a musical rhythm continually running in her mind. Day and night the automatic repetition of tunes and musical cadences ran constantly through her mind. Upright or recumbent, in the waking state or in her fitful sleep, the automatic rhythm persisted. She thought and dreamed of music and felt its rhythmical influence continually throughout her nervous organism. Her pulse was rapid, her heartbeats were over-forceful, her pupils were abnormally mobile and dilated, her digestion was tardy but finally adequate, the bowels were torpid, the skin was relaxed, and she felt continually tired. She recovered under rest, change of environment, cessation of study and piano practice, withdrawal from musical companionship, brain-tranquillising galvanisations, ether-menthol evaporating lotions to the head, chemical brain restraint, and pepsines and laxatives. Had she continued much longer in her vicious course of incessant overstudy this handsome and promising girl would have passed from the morbid psychical automatism of neurasthenic excitability into positive insanity, as I have seen others pass, especially ambitious, self-sustaining teachers, to go beyond the line that marks the morbid psychical automatism of incessant overaction into the realm of actual insane aberration. These cases can be saved if treated in time by the alienist and neurologist, but not by any local treatment outside of the brain, unless perchance the change of environment and its influences are of so tranquillising, diverting, and restful a kind as to bring about through Nature's unaided resources the needful recuperation of the nerve instability and morbid automatism of brain overtax. If these unfortunate persons get only throat treatment they are likely to be lost, unless perchance the brain-rest from cessation of work and changed environment should bring about a cure.

A young unmarried man, who speedily became hopelessly insane and soon after died demented, displayed the beginning of his breakdown by exclaiming *sotto voce* while riding with me, "Beethoven! Beethoven!" This he would continually repeat. An aged lady, over 70 years of age, who became somewhat demented, would often repeat, "Yes, I love God! Yes, I love God!" in the midst of conversation and when alone.

A music teacher and composer of great genius, and now perfectly well, could not refrain when he first saw me from going through the movements of fingering the key-board of the piano and a tra-la-la accompaniment. He had just finished a Herculean task and was on the verge of a disastrous breakdown characterised by profound insomnia, marked general restlessness, and psychical excitability.

A charming young lady patient under my care at the asylum at Fulton, Mo., in 1870 first attracted attention by repeating a call to the chickens, of which she was very fond when at home. "Chicky, chicky, chicky," she would repeat, and as her insanity became pronounced she would say "Chicky" all day and far into the night until put to sleep by hypnotics. A suppression of the menses accompanied or preceded her insanity and returned with the return of her sanity. She recovered after six weeks' treatment with bromide of potassium, timely hypnotics, tonics, aloetic laxatives and gelsemium.

Another patient under my care at Fulton, a man of upwards of 50 years of age who had gone insane and had turned grey in a few weeks' time under the strain and misfortune of the Civil War, having lost most of his property, principally in slaves, and become suddenly bankrupt, assumed a bent-over attitude as he walked about night and day exclaiming, "My God, how can I stand it; how can a man carry the world on his shoulders?" This man, who was possessed of good physical vigour for his years and was an excessive user of tobacco, reminded me of the pictures of the mythical Atlas. After the acute stage of his malady had passed he would repeat only the words "How can I stand it?" and this utterance he would make years after the inception of his insanity, even at times when provoked to smile or when asking for a chew of tobacco, after the fires of the early mental conflagration had gone out and his life seemed to be no longer one of psychical pain. The scar remaining among the cerebral cinders kept up the automatic cerebral refrain, "My God, how can I stand it? How can I stand it?" long after he had ceased to feel the poignant mental pain of the acute stage of his disease.

The peculiarity of Samuel Johnson who, after a good deal of mental strain, could not pass a single one of the stone posts which stood at regular intervals along the pavement of the streets in his native town of Lichfield without laying his hand on the top of each one is also *apropos* to our subject. Fortunately Johnson never broke down seriously in his nerve centres. His repetitional automaticity did not pass to an extremely morbid stage.

Under the heading of "Letter Counting," the Paris correspondent of the *British Medical Journal* mentions a case in point reported to a Bordeaux society by Dr. Ginostos. The subject was a young man who since the age of 10 years had had an irresistible impulse to count the letters in a word or phrase that he heard, saw, spoke, or thought. At night he slept without dreaming. When he did not talk he invented phrases and counted the letters in them. 32 was a number that gave him satisfaction; the number 13 displeased him, but nevertheless he did not recoil from arranging phrases with 13 letters in them. This unceasing automatic operation did not in any way interfere with his daily work or his reading or with the carrying on of a conversation. A reference to this interesting case appears in the columns of a number of the *New York Medical Journal* which I do not at present recall. Echolalia, coprolalia, &c., are likewise somewhat germane to this subject as showing a similar but graver state of repetitional impulse and obsession, but rhythmic repetitional automaticity is what we are now considering. There are likewise references of interest, not wholly *mal-apropos*, in Forbes Winslow's "Obscure Diseases of the Brain and Mind." Indeed they may be found in many books devoted to psychiatry.

I have heard a chronic alcoholic repeat over and over through the day, "Little Bo-Peep, he lost his sheep, and doesn't know where to find them," &c., and have known chronic lunatics who would repeat some long-ago-learned distich or rhyme or some insanely-constructed jingle of words in maudlin monotone, from the day's beginning to the ending thereof, in all their waking hours, some of them singing their peculiar song, like the dying swan, to the end of their unfortunate lives. Some would recite their phrases backward, a transposition from the way in which the verses were written. If we carefully scan the speech and song of the insane we will find much not yet recorded and many forms of this morbid psychical display of automaticity. It has as many peculiarities of expression as the singularities of writing and speech in agraphia and amnesia and other forms of aphasia. More extended rhyming forms of speech or song, evincing mental spontaneity and sometimes marked ability of improvisation among the insane, are interesting and common in hospitals for the insane, but they do not strictly belong to our present subject. The following case has been reported by Forbes Winslow:—

> A lady who had been 18 months insane detailed to me, after her recovery, the symptoms that characterised her derangement. She [illegible] usly to her being considered [illegible] she was not "quite herself." [illegible] out of order and I had a [illegible] by great debility which con- [illegible] was during this illness that my foolish fancies began to annoy me. At this time I used to talk out loudly to myself, a thing I never did before. This was irresistible. I ejaculated the most foolish remarks, and at times, too, with wonderful volubility of speech. I did my best to control myself in this particular, but found it difficult to do so. I was quite conscious that my mind was affected, and yet no delusion had taken possession of my intellect. For several days I succeeded, by strong efforts of thought, in checking this ridiculous inclination to utter absurd expressions, but I awoke one night in an excited state, from a troublesome dream, and I began then to vociferate a number of most incoherent expressions to this effect. 'You shall do it.' 'No you sha'n't.' 'He is like Satan.' 'Why don't you say the devil?' 'Ah! Ah! Ah!' 'It is beautiful.' 'No he devils.' 'I can't be saved.' 'You have no hope.' 'Suicide.' 'Poison.' 'Hang yourself.' 'They are after you.' These strange remarks continued for nearly two hours, when I fell asleep, and arose much relieved. My mind, however, was for some time afterwards not in a right state, although I had intermissions from the misery I suffered. Eventually I became quite insane and I am informed remained so for nearly 11 months. During the [illegible] hell and tormented by evil [illegible] to be a devil. My mind was [illegible] cannot say when I first began [illegible]

I should like as forcibly as possible to call your attention, as I think Forbes Winslow has done before me, to the significance of absent-mindedness, abstraction, inattention, and what since Carpenter we have called "psychic automaticity," as precursors of mental aberration. Of course, these states signify little unless they are progressive or until they have reached the verge of morbidity with profound and uncontrollable disregard of the proprieties and harmonies of environment. Nevertheless, they are worthy of note and mean much very often to the closely observant alienist clinician. They may serve to start him in the right direction of search for grave impending psychical malady in its avertable stage.

I saw once a charmingly-voiced lady suffering from this form of cerebrasthenia and neur[illegible] while abroad cultivating her voi[illegible] rhythmical, chanting, psychical [illegible] while mistakenly having her thro[illegible] She once consulted me. I saw the impending catastrophe and could have averted it, but was not asked to treat her further and my further advice of prompt brain-rest and nerve recuperation was not followed and the catastrophe came. Her trouble began with musical cerebrasthenia.

A young manustupral neurasthenic was brought to me by his father some years ago. During my first examination of him he interrupted the proceedings, exclaiming, "It don't correspond." He had been a studious youth of good morals, and his mind was probably vaguely reverting in automatic manner to some problem in mathematics worked at in other days. I could not get him to say what he meant or to take treatment. After that he passed speedily into stuporous dementia and soon died. His mother was neurotically enfeebled at the time of his birth and his malady was evolutionally predestined, the masturbation having been an incidental developmental sequence probably as well as a contributing cause.

A gentleman of extensive business affairs who came to me on the verge of financial and business bankruptcy, but who is now after many years of health successful in a new but less harassing line of business, would continuously say to himself: "Too many irons in the fire, too many irons in the fire." His intellect was clear but his brain was jaded and unstable—in that stage of cerebrasthenia that so often precedes the final brain-break of insanity. The closing out and winding up of his business saved him for recuperation and another and less harassing and more successful career. These cases are significant to the neuro-psychological clinician and they are amenable to cure if timely treated and if we are not misled from the brain, which is the central origin of the trouble, to the peripheral symptomatic expression. Insomnia and other forms of restlessness precede and accompany their expression, as likewise do disturbed visceral states dependent upon vagus innervation. Like most voice failures and many altered chirographical expressions, the autographs of morbid brain and nerve states, as in general paralysis and disseminated and posterior spinal sclerosis, the disease is not in the organs of expression in which the symptoms show, but chiefly in the brain, the allied peripheral neural mechanism only subserviently participating. Other clinical illustrations might be cited from my experience, as, for example, some forms of choristers' and pianists' palsy, &c., but these are omitted for the sake of essential brevity and to avoid possible contention. To an audience of *savants* like that before me one word will suffice for many.

This morbid state of the nervous system is so distinctively peculiar as to be entitled to distinctive designation. All have observed it, especially those who have added to their neurological experience opportunities for extensive observation in psychiatry. It is a symptom and precursor, if unarrested, of insanity, and though it may stop short of the greater *dénouement* by fortuitous change in the life habits or thorough, timely, skilful treatment of the individual, it is a serious condition of the brain demanding our best thought and effort for its prompt relief and calling for cautious, forceful admonition as to the impending peril of its persistence. I have used, for want of a better term, "autopsychorhythmia," since under the dominance of this morbid state of brain and mental expression the mind loses to a degree its volitional spontaneity and becomes abnormally automatically rhythmical in psychical feeling and expression. And when the stage of insanity is reached the mind so expresses itself, regardless of the proprieties of place or occasion and out of normal harmony with rational environment. The distinction between morbid and normal autopsychorhythmia is in the persistent and inopportune obtrusion of the rhythmical repetition in manner not in harmony with the environment of the individual. The will does not attempt its suppression, or, if it does, it cannot, when and where the proprieties demand it, whereas within normal limits it selects suitable occasions for permitting the rhythmical repetitions that run through the mind to go on uninterruptedly and can effectually check them on proper occasions. All perfected education of the psychical neuron centres develops an automatic aptitude for easy repetition. This is not a morbid feature of mental action and is not what I have attempted to describe. It is the morbid aspects of this mental state, when normal regulated control is impaired and, in the graver conditions, lost, to which I invite attention as of significance to the neurologist and alienist. It is evidently a lesion, more or less grave, of the psychical inhibitory centres that claim our consideration and demands attention from the profession that it has thus far not adequately received. There is a neuriatrical with a psychiatrical, as well as a psychological, side to this interesting and important subject. It is the second to which I would call professional attention.

Involuntary psychical automaticity in many forms, including the feature which we are now discussing, is a forerunner of grave insanity which displays itself paramountly in lessened inhibitions of normal mental action as well as in impulsions to erratic conduct and in the many forms of automatic mental aberration revealed in the actions and speech of the acknowledged insane, both within and without asylums. All symptoms, therefore, which point in that direction, even though remotely, claim thorough investigation and prompt remedial endeavour. Brain strain like that under discussion passing the line of morbid autopsychorhythmia is always a matter of gravity and solicitude. It is the limp that precedes the paralysis of the mental gait—the beginning spasm of overuse that may end in wrong movement. The brain thus going wrong should be made to rest and be brought back by neuropsychological treatment into habits of normal action.

Dr. Martin W. Barr[1] has discussed an interesting subject akin to our theme and rather more germane to it than the various forms of aphasia under which it is generally considered—namely, echolalia. Hammond, quoting from Winslow, gives the case of a woman who always said at her prayers, "Our Father which art in hell," meaning to say "heaven," and the case of a man from his own observation who said automatically, "Saw my lew off," to any question asked. There is no connexion, in my judgment, between my subject and any form of hypothetical transcortical aphasia or the motor aphasia of Broca's speech-centre. It is neither echolalia nor coprolalia, though I agree with Tuke that echolalia and coprolalia, as some forms of aphasia and other speech-defects do, portend, like autopsychorhythmia, insanity. They are morbid impulsions, and morbid impulsions are lesions of inhibition not far in advance of oncoming psychical aberration. Coprolalia, a tendency to express as well as to repeat foul language, is often heard among the insane, even among naturally modest and cleanly-minded women. Mills[2] records the case of a refined and cultured lady who would suddenly swear and gesticulate, and that of a boy who would suddenly utter filthy language and move his head, shoulders, and arms violently. These are common symptoms in the observation of insanity. These two cases are quoted by Barr as combining palmus or myriachit and coprolalia, as they undoubtedly do. But the Jumpers of Maine are victims of impaired volition and psychomotor irritation and some of them are not far removed from insanity. Mills then very properly classes echolalia under morbid impulse rather than under aphasia[3] and had he rested there he would have remained on undebateable ground but in a later article, as Barr observes, he classes true echolalia as a characteristic symptom of transcortical sensory aphasia.[4]

A similar but not the same state of mind as that of autopsychorhythmia may be seen in the feeble-minded as in the volitional repetitions of Barr's pupils at Elwyn, Pa., which he describes as echolalia. The boy Kirtie repeating "Kirtie, come to school to-morrow; Kirtie, come to school to-morrow morning," &c., is similar but not the same. It is the voluntary habit of a feeble mind to fix a mental impression. Something similar is sometimes also the habit of the infantile mind when learning to speak.

ADDENDUM.

The form of insanity in my observation to which autopsychorhythmia tends is that in which imperative conceptions predominate or have predominated in the initial stage of the mental disease. In aggravated form it is an imperative, resistless impulse to repetition of psychical impression in the form of verbal expression. In the Dictionary of Psychological Medicine Tuke broaches this subject under the definition of imperative ideas, but he does not compass it. He briefly discusses them under echolalia and certain of the morbid fears of neurasthenia, but my subject does not include morbid fears, illusions, or hallucinations, though they may coexist with it. Psychorhythmia is a tendency of the mind more or less resistless to repeat continually and non-volitionally its once volitional actions even at inopportune time and place. It is a habit volitionally induced which has passed into a morbid automatic impulse associated with brain overstrain or excitation. The habit excites the patient's concern and sends him, if he is an intelligent man, familiar with the possible resources of psychiatry, to seek relief in special medical advice and remedy. When this condition displays itself in unrestrained impulse of speech or song to the chagrin of the individual and the surprise of his friends it is an act out of harmony with his rational character and environment and is then initial insanity.

Another feature of our subject is shown in a tendency to imitative acts, such as grimaces and stuttering and spinal-cord and motor-centre movements (jumper's palsy), which by often and long repetition have become organised automatic impulsions no longer volitional with the individual and which sometimes are seen to pass into the acts of the insane. To discuss these now *in extenso* would make this paper too prolix. In the *Alienist and Neurologist* for January, 1897, under the heading "Imperative Conceptions," I have discussed more *in extenso* this subject. I have there recorded the case of a victim of coprolalia who upon being advised to quit breaking out with sudden profanity, said: "I can't; I would that I could. I go about my work crying and talking. I will say, 'I will not do that any more,' and it will not be five minutes until I will be at it again." "I think and say such awful things. I never did so before and do not believe I want to now."

Discussing echolalia Dr. Martin W. Barr records a case under his observation of a beautiful and refined girl attending a boarding school who would at intervals give sudden expression to three words successively, the first vulgar, the second foolish, and the third profane.[5] This condition in some of its features is related when in intense morbid degree to our subject and proves its psychopathic basis and affinity with psychorhythmia. Morbid autopsychorhythmia has relation to the spasmodic word outcries of the insane—coprolalia and echolalia, &c., similar to the rhythmical spasm of athetosis in comparison with the jerky spasm of tetanus, chorea, or the spastic movement of lateral sclerosis.

The pathological lesion of autopsychorhythmia is evidently in the mind area of the brain cortex. It is truly transcortical and not localised exclusively in the speech area. It is a psychical and not purely psychomotor involvement—a psychical lesion shown in peculiarity of psychomotor expression. If in "this frame the bearings and the ties, strong connexions, nice dependencies," an ancestral "blot upon the brain" has left for transmission a latent hereditary scar of aberrant mental action, we may expect to see the psychical perversion of insanity develop under stress of brain and mind, such as destroys or weakens its normal regulating power. "That way madness lies; let us shun that." It may show in obscure, if not in plainer form, or in mental eccentricity, and thus mark and mar the after-life.

St. Louis.

CORRESPONDENCE BETWEEN CHOLERA AND THE PREVALENCE OF COMMA BACTERIA IN WELL WATERS OF GUJERAT DURING THE FAMINE OF 1900.[6]

BY GEORGE LAMB, M.B., C.M. GLASG.,
CAPTAIN, INDIAN MEDICAL SERVICE.

(From the Research Laboratory, Bombay.)

AT the end of May of last year, on the suggestion of Mr. Haffkine, I was deputed by Government to make a short tour through some of the famine districts in Gujerat. The object of this tour was twofold: (1) to ascertain if the high mortality from a disease which was being returned under the name of "fever" could be accounted for by the presence of an epidemic of relapsing or spirillum fever; and (2) to examine as many water-supplies as possible for the presence of comma-shaped micro-organisms. This investigation was undertaken with a view to finding out whether any relation could be traced between the incidence of cholera and the prevalence of these organisms in the drinking waters. It is the result of the latter of these researches which I propose to put before you this evening.

---

[6] A paper read before the Bombay Medical and Physical Society on Jan. 18th, 1901.

Unfortunately, by the time I arrived on the scene the cholera epidemic had practically spent itself. It was then limited to sporadic cases in some of the districts, while in other districts it had completely died out. The investigation, however, was not without results, which if fully confirmed and extended would do much to assist us in combating epidemics similar to that which swept through the famine districts of Gujerat.

It would be well at the outset to give a brief outline of the methods which were employed in this research. These may be stated as follows. On arriving at a locality samples of as many well waters as possible were collected in small sterilised bottles. If sterilised bottles were not available each bottle was first washed out many times with the water which was to be examined. Each sample was as soon as possible after collection planted into a solution of peptone and salt (1 per cent. peptone and 0·5 per cent. salt). This culture medium, which, as is well known to all of you, favours greatly the growth and propagation of comma-shaped bacteria, was prepared as required by boiling in a small pot for one hour the requisite amount of peptone and salt in ordinary water. The solution was then allowed to cool. When cool it was divided up into ordinary wine-glasses which were covered over with pieces of paper. Both the wine-glasses and pieces of paper had been previously sterilised as far as possible by boiling them for from half an hour to one hour. The wine-glasses after insemination with the water were kept absolutely still so as not to disturb and to break up any veil which might grow on the surface. It is necessary to remark that on this medium the early growth of all comma organisms takes place on the surface where there is free exposure to the oxygen of the air. Incubation was allowed to go on for from 18 to 24 hours at room temperature, which ranged between about 80° and 100° F. Zigzags on agar slopes were then sown from the veil which had grown on the surface of the peptone, three tubes of such being prepared without recharging the needle. In this manner isolated colonies of the various bacteria which happened to be present in the veil were readily obtained for further investigation. At the same time a dry film preparation on a slide was made from the veil. All specimens, both agar cultures and slides, were at once despatched to the laboratory in Bombay for detailed examination. This examination was undertaken by Dr. Hanna and was finally completed on my return at the end of the tour. To each specimen and culture a distinguishing number only was affixed. In my notebook a description of every preparation was entered. I also carefully noted the place where these were obtained and the condition as to the prevalence of cholera there. In this way the examination of the preparations prepared by me was made independently by a man who had no knowledge of the source of the specimens. The final result was compiled by putting together these two sets of records—my own and that which was made and kept by Dr. Hanna in Bombay.

Every comma-shaped or spirillar organism isolated and obtained in pure culture was subjected to the various bacteriological tests which are used to differentiate the true cholera vibrio from other non-pathogenic commas and spirilla. It is quite unnecessary for me to enter into the details of this long and tedious investigation. It is sufficient for our present purpose to state that some of the bacteria isolated were easily differentiated from the cholera comma. On the other hand, in one or two instances it was only by means of the serum agglutination test that such a distinction was possible. This test, as you know, consists in bringing the micro-organism under investigation in contact with the diluted serum of an animal previously treated by injections of a known cholera vibrio, or *vice versâ* by treating an animal with injections of the suspected microbe, and then bringing in contact the diluted serum of this animal and a culture of a known cholera germ. In either case, if we are dealing with a true cholera organism, immobilisation, agglutination, &c., of the bacteria quickly take place. Briefly, then, I may state that the result of this research was to show us that not one of the comma-shaped bacteria which had been isolated from Gujerat waters could be termed a true cholera vibrio. There was, however, no doubt, as judged from their appearance under the microscope, their staining reactions, and their growth on different media, that they all belonged to the tribe of curved bacteria, which includes the true cholera-producing microbe.

After this point had been settled the next question was to ascertain what relation there was between the presence of these comma-shaped organisms in the waters of a district and the prevalence of cholera in that district. The data which bear on this question are as follows (*vide* Table I.):—

TABLE I.

No.	Locality.	No. of wells examined.	Commas present or not.	Condition as to the prevalence of cholera.
1	Broach Poorhouse.	One.	Present.	15 cases in all among recent arrivals; last case 11 days before.
2	Maturia Tankworks.	Two.	Present in both.	Cholera very prevalent—about a month before; at time of examination only four or five cases daily.
3	Wansar Tankworks.	Three.	Commas in one well only.	14 cases of cholera in all; last case five days before examination.
4	Kaira Missionhouse.	One.	Absent.	No cholera at time of inquiry. Cholera had been prevalent some time before.
5	Matar Poorhouse.	Two.	Present in one only.	33 cases of cholera in all; last case two days before examination.
6	Nadiad Poorhouse.	One.	Present.	No cholera for the 39 days before examination. *Recrudescence shortly afterwards.*
7	Nadiad Town.	Three.	Present in two.	Sporadic cases at time of examination. Recrudescence shortly afterwards.
8	Anand Poorhouse.	One.	Present.	62 cases of cholera in all; last case five days before examination.
9	Anand Village.	One.	Present.	Cases occurring sporadically.
10	Dakor Tankworks.	Six.	Absent in all.	Cholera very prevalent in April, when works had to be closed. Re-opened in beginning of June; no case had recurred. Examination on June 12th, 1900
11	Godhra Town.	Four.	Absent in all.	No cholera since a month.
12	Godhra Poorhouse.	Two	Absent in both.	No cholera since a month.
13	Dohad Poorhouse.	Two.	Absent in both.	No cholera at time of examination.
14	Dohad Town.	Four.	Absent in all.	No cholera at time of examination.

1. *Broach Poorhouse.*—One well; comma-shaped organisms were found in this well. 15 cases of cholera had occurred here, the last case 11 days previously to the examination.

2. *Maturia Tankworks.*—Two wells; comma-shaped bacteria were found in both. Cholera had been very prevalent about a month before. At the time of examination only four or five cases were occurring daily.

3. *Wansar Tankworks.*—Three wells; commas very like the cholera vibrio, and only able to be differentiated by means of the serum agglutination test, were found in one well. The other two wells were free from any comma vegetation. 14 cases of cholera had occurred in this camp. The last case had been admitted into hospital five days before the examination of the water.

4. *Kaira Missionhouse.*—One well; no comma-shaped organisms were found. There was no cholera here at the time of inquiry. It was reported, however, that some severe sickness, but not known of what kind, was prevalent; cholera was stated to have raged some time before the examination of the well.

5. *Matar Poorhouse.*—Two wells; commas were found in one only. 33 cases of cholera had occurred in this poorhouse previously to the examination, the last case only two days before.

6. *Nadiad Poorhouse.*—One well; comma-shaped micro-organisms were found in this well. No case of cholera had occurred among the inmates since 39 days.

7. *Nadiad Town.*—Three wells; commas were found in two out of the three. Sporadic cases of cholera were still occurring in this town, but they were not severe.

8. *Anand Poorhouse.*—One well; a comma-shaped micro-organism closely resembling the cholera vibrio was isolated from this well. 62 cases of cholera had occurred amongst

the inmates. The last case had been admitted into hospital five days before the examination of the well.

9. *Anand Village.*—One well; commas were found in this water. Sporadic cases of cholera were still occurring in the village.

10. *Dakor Tankworks.*—Six wells; no comma-shaped bacteria were found in any of these wells. Cholera had raged among the workers at this camp with such force during the month of April that the works had to be completely closed. They were opened again in the beginning of June. Since then no cases of cholera had occurred up to the date of the water examination (June 12th).

11. *Godhra Town.*—Four wells; no commas were found in any of these wells. No case of cholera had occurred in the town of Godhra itself since about a month. At the time of the water examination a few convalescent cases were being treated in the hospital. These cases, however, came from some outlying villages where the disease was still sporadic. There was no recrudescence of cholera in Godhra itself till two months after my visit.

12. *Godhra Poorhouse.*—Two wells; no comma-shaped bacteria were found in either of these wells. No case of cholera had occurred in this poorhouse since a month.

13. *Dohad Poorhouse.*—Two wells; no commas were found in either. There was no cholera in this poorhouse at the time of examination.

14. *Dohad Town.*—Four wells; no curved microbes were found in any of these water-supplies. There were no cases of cholera occurring in Dohad Town at the time of my visit there.

From the above synopsis it will be seen that 33 well waters in 14 different localities were examined. In eight of these localities comma-curved bacteria were found, while in six they were absent. In seven of the eight localities just named cases of cholera were still occurring either daily or at intervals, the last case having occurred two, five, five, and 11 days before the samples of water were taken. In one place only of the eight—viz., the poorhouse at Nadiad, to which reference will be made further on, there had been no case for the last 39 days. On the other hand, in all of the six localities where no comma-curved bacteria were detected in the laboratory my notes show that no cases of cholera were occurring at the time when the water-samples were collected for examination. There was thus a marked correspondence between the prevalence of this disease and the presence of curved micro-organisms in the water-supplies. In the case of the poorhouse at Nadiad there had been no cholera for 39 days, although curved bacteria were found in its well. Cases, however, continued in the town, and shortly after my visit Mr. Swift, the personal assistant to the Collector of Kaira, informed me that a severe recrudescence of the disease had occurred in the locality. The finding of curved bacteria there may therefore have been due to a recent re-infection of the well. The poorhouse had been practically vacated at the time of the inquiry (during the preceding week the population was reduced from 500 to 66 inmates) and such re-infection may not have had time to show in the form of cholera cases.

The above relation between the incidence of cholera in a locality and the presence of curved comma-shaped micro-organisms in the waters obtains an enhanced significance from a comparison with the result of a similar investigation which Mr. Haffkine and Dr. W. J. Simpson, then health officer of Calcutta, made into the distribution of curved bacteria in the tanks and other reservoirs in Calcutta during April, 1894. A detailed account of this research is to be found in the *Indian Medical Gazette* of March, 1895. On that occasion 82 specimens were examined; these were taken from 211 localities. 432 of these specimens were from 110 tanks, while the other 150 were taken from private wells, from drains, from the river Hoogly, from the canals, from bathing platforms, from street hydrants, in milk markets, &c. No relation between the cholera outbreak and all the last-named sources was detected. The tanks, however, gave the following result. Of the 110 tanks examined (1) 46 were tanks round which cholera existed at the time of the examination; (2) five were tanks round which cholera had existed from a month to six weeks previously and had disappeared since; and (3) 59 were tanks round which cholera had not appeared at all during the four months of 1894. Out of the 46 tanks of the first category comma-shaped organisms were found in 42—i.e., in 91 3 per cent.—and missed only in four. Out of the five tanks of the second category curved comma bacteria were found in none. And out of the 59 tanks of the third category commas were found only in 11—i.e., in 18·8 per cent.—and were not found in 44—i.e., in 81·4 per cent. The comma-shaped bacteria found in these tanks varied greatly as to their detailed characteristics, but all belonged to the class of curved bacteria which have the faculty of turning into spirilla and long threads when grown under suitable conditions. It may further be noted that these Calcutta commas and spirilla were not subjected to the serum agglutination test mentioned above. It is therefore more than probable that only a small proportion of these organisms were real cholera-producing bacteria.

The prevalence of comma-shaped micro-organisms which although not the true cholera vibrio belong to the same tribe in places where cholera exists and their absence from places free from cholera is a fact somewhat difficult of interpretation. Mr. Haffkine, commenting on this point in a recent report to Government, put forward the following hypothesis. He says that such results can best be interpreted by the supposition that the whole tribe of curved bacteria, including the typical cholera vibrio, requires for its existence similar or very comparable conditions, and that on the one hand wherever these conditions are inimical to the cholera germ, no curved bacteria of any kind are to be met with; and, on the other hand, wherever the local conditions are favourable to the growth of curved bacteria in general the true cholera-producing microbe develops and propagates in large numbers, causing an outbreak of the disease in the adjacent population. The results which were obtained in Calcutta and in Gujerat, if observed and confirmed in a number of similar instances, would tend to show that without having any information as to the actual prevalence of cholera in the districts the bacteriological examination of the waters would give a useful warning as to the danger from cholera which exists in those districts. Thus, as already mentioned, of the 14 localities in Gujerat where the waters had been taken from eight—viz., Broach Poorhouse, Maturia Tankworks, Wansar Tankworks, Matar Poorhouse, Nadiad Poorhouse, Nadiad Town, Anand Poorhouse, and Anand Village—showed themselves in the laboratory examination as presenting such a danger. The others would have been returned as free from cholera. Further, it is evident that some practical advantages may be derived from such an investigation as was carried out by this laboratory in Gujerat and by Mr. Haffkine and Dr. Simpson in Calcutta. These advantages may be briefly stated as follows:—

1. In a place vacated on account of cholera the examination of the water may help to determine the date when it becomes safe to return to the place. Thus, in April the Dakor Tankworks had to be vacated on account of cholera. In June the water-supply was examined and showed no comma-curved bacteria. As mentioned above, the people who were permitted to return during the month remained free from cholera.

2. In a place where there are only a few sporadic cases of the disease a similar examination may give warning if a serious outbreak or recrudescence is threatening. Thus, at the time of the water examination at Nadiad in the poorhouse there had been no cases for 39 days and in the town the disease existed only in a mild form. But an examination of four wells revealed in three the presence of comma-shaped bacteria. In apparent connexion with this result cholera broke out again in this locality shortly after.

3. In a locality where cholera is epidemic the bacteriological examination of the water-supply may reveal those sources which are dangerous. Now, by closing such dangerous sources or otherwise preventing the people from using the water from them, the necessity for vacating the whole locality may be avoided, and at the same time the occurrence of cases prevented. Thus among the Calcutta tanks cited above often such as were situated in close proximity differed in that some of them were free from comma vegetation and others were infected. And in accordance with this the huts situated round the former were free from the disease while those round the latter produced cases of cholera. It is evident from what I have stated that the data bearing on the question under consideration which have been collected up to the present do not permit of establishing any connexion between the result of the laboratory investigation and the exact course which an epidemic of cholera is likely to take—viz., whether it is likely to decline or to increase. For this

purpose many researches into the prevalence of these comma-shaped micro-organisms in the water-supplies at the beginning of an epidemic, during the height of the epidemic, and during its defervescence would be required.

In conclusion, I have to bring to your notice the data contained in Table II.

TABLE II.

When or how often the wells were treated with permanganate	Number of wells so treated.	Whether commas were absent or present.
The day before examination	One.	Present.
Two days before examination	Two.	Present in one; absent in one.
Regularly every day	Three.	Present in one; absent in two.
Twice a week	Six.	Absent in all.
Once a week	Five.	Present in two; absent in three.
Stated to have been treated repeatedly	Three.	Present in all.
Stated to have been treated with permanganate .. .	Four	Absent in all.
Had been treated only once	One.	Absent.
Had not been treated	One.	Present.
No information obtained ...	Seven.	Absent in six; present in one.

In this table the result as to the presence or absence of comma-curved bacteria in wells is put side by side with the information noted in my notebook as to the treatment with permanganate of potassium which the wells were stated to have undergone. The result is as follows: 1. Of the 25 wells, about which it is reported that they had been treated with permanganate, some more frequently and others less, eight contained commas. The 17 other wells treated were free. 2. In one well that had not been treated commas were found in numbers. Neither these facts nor the analysis of the connexion between the frequency of the treatment and the absence or otherwise of the commas, as shown in Table II., permit of drawing any definite conclusion as to the efficiency or otherwise of the permanganate process of treating infected waters.

Bombay.

WHEN TO OPERATE IN PERFORATIVE PERITONITIS.[1]

BY ARTHUR C. ROPER, F.R.C.S. EDIN.,

SURGEON TO THE ROYAL DEVON AND EXETER HOSPITAL.

I HAVE found during the last few years that considerable difference of opinion exists among us as to the occasions and the time for opening the abdomen in serious and sudden emergencies, and since I think it will be useful for us carefully to consider and to discuss the question I propose as a basis for such discussion to give you the *main principles* upon which my practice in such cases is founded. One paper would not suffice to deal with all the abdominal emergencies in which laparotomy is, according to modern surgical practice, demanded, so I propose to discuss in this paper one of the commonest, and therefore most important, clinical groups—viz., perforative peritonitis.

The diagnosis is the first important matter that we have to settle, and we must in many cases settle it quickly if we are to save our patient's life by operation. I remember a case of perforating ulcer of the duodenum in a patient of mine who died within 14 hours of the perforation without rallying in any proper sense of the word from the initial shock. The case occurred before the days when operation in these cases was generally practised, and the post-mortem examination showed that the ulcer was in an inaccessible situation at the back of the duodenum; but the point which I wish to press home is the extreme urgency of these cases and the fatal danger of delay. The diagnosis, then, has to be made and made at once if possible, so let us consider with what lesions perforative peritonitis—i.e., peritonitis caused by the rupture or ulceration, actual or potential, of some viscus or abscess into the peritoneum, and the diffusion of its contents over that sensitive lymphatic area—may be confounded

Gall-stone and renal colic we must mention. We are not likely to confound them, although I have been in doubt about such cases. The onset is not very dissimilar, but in other respects the conditions have not much in common. Peritonitis non-perforative in origin is, of course, the chief crux, and here I find my surgical sense asking my medical conscience this question—"Do you really believe in a peritonitis which has its origin in a cause not remediable by surgical treatment?" and if you except the rare but well-known and easily recognisable cases which arise from a septic condition of the system such as those which occur in the course of scarlet fever, puerperal septicæmia, pelvic cellulitis, and the like, I must say that I do not. Tuberculous peritonitis may be named together with a ruptured hydatid, but both are more or less surgical conditions. I hear occasionally of peritonitis from exposure to chill, but I cannot honestly say that I believe in chill as a real and fundamental cause of the disease. There are many causes other than perforation, but most of them would be dealt with in a paper on intestinal obstruction, and they require consideration from the surgical point of view.

We are called, say, to a case of perforated gastric ulcer. We arrive soon after perforation has occurred and we find the patient in agony. Everything shows us that it is so and that the case is most serious. The patient's aspect is one of terror and expectancy—terror of the fearful pain which is every moment increasing in severity until it threatens to overwhelm sense and life. The terror-stricken look is that of shock—pallor, sweating, starting eyes, parted lips, and clenched teeth are all there. The pinched nose and sunken cheek give the facies abdominalis and afford you the first clue to your diagnosis. Is the sufferer rolling about in the bed? If so it is probably not peritonitis but a colic, intestinal, biliary, or renal Patients with peritonitis keep their abdominal muscles very still. They may toss the arms about or roll the head in the restlessness of severe pain and collapse, but they do not move the abdomen. You will probably observe or hear that vomiting has occurred, and retching may be actually in process at the time of your visit. Too much stress must not be laid upon this symptom, because in perforation of the stomach, if the stomach is empty at the time there may be little or none, and even if a meal has been recently taken the first copious vomit rids it of its contents and the symptom ceases. Persistent vomiting is a symptom rather of intestinal obstruction than of perforation. The temperature is unimportant at this early stage, but it is most likely to be subnormal during the first few hours. You next feel the pulse, and it is the pulse of shock in a typical case—small and rapid—though I have seen cases where its pace has been scarcely at all accelerated. Then, if you have not already heard the story of the commencement of the attack you inquire and you find that it has been more or less sudden. There may have been a slight similar attack which passed off rapidly a short time previously, but if you have not been attending and guarding against such a catastrophe *as has occurred you find that it* has come on without warning. Possibly your patient has been sitting still or even asleep in bed, though more usually some slight exertion seems to have determined the attack. By this time you have a strong suspicion of peritonitis, and your mind then travels rapidly over the few viscera the, perforation of which may have caused it—viz., the appendix, the stomach, the intestine, the gall-bladder, or, in a woman, the Fallopian tubes and ovaries. I have seen within the last three weeks two cases of pelvic cellulitis in which the onset of peritonitis exactly resembled that of perforation. To guide you further you put a few leading questions as to the organ from which the lesion originates. First, the appendix. Has there been any previous illness, with abdominal pain, constipation, and tenderness in the right iliac region? If so, how many attacks and at what intervals? Next the stomach. Any indigestion, flatulence, or pain after meals? If so at what interval after? Especially must inquiry about vomiting, hæmatemesis, and melæna be made. Thirdly, the intestines, which rarely perforate save in diarrhœa from typhoid fever or in tuberculous ulcer. *Fourthly*, the gall-bladder. Jaundice and gall-stone colic with tenderness.

---

[1] A paper read at a meeting of the Devon and Exeter Medico-Chirurgical Society on Feb. 15th, 1901.

Fifthly, the Fallopian tubes and ovaries. In this connexion you must think of ruptured tubal pregnancy which is remarkably like perforated gastric ulcer in its onset. Pyosalpinx, bursting into the peritoneum. Pelvic cellulitis I have already spoken of. In connexion with the ovaries you will inquire for the presence of a tumour which may have disappeared, for there may have been a ruptured cyst, or a suppurating cyst, or a cyst the pedicle of which has become twisted. Having obtained as much information as you can get or require without harassing your patient you proceed to examine the abdomen. Be careful to have it thoroughly exposed and in as good a light as possible. In the early stage of peritonitis you will almost certainly find that the abdominal respiratory movements are either greatly diminished or altogether absent and that there is rigidity of the abdominal muscles. There is no distension at this period, unless it pre-existed, but peristaltic movements may sometimes be seen. Palpation elicits in addition to the rigidity that the abdomen is tender, probably exquisitely so, but this depends in great measure on the ability of the patient to endure pain. Percussion, lightly performed because it is painful, will, if two or three hours have elapsed since the perforation, tell you that there is fluid in the flanks, a most important sign, and further it may furnish you with evidence of free gas in the abdomen by showing diminished liver dulness. If this free gas is clearly demonstrable it places the diagnosis of perforation of the stomach or intestine beyond reasonable doubt.

I have enumerated the four cardinal signs upon which I am accustomed to rely for my diagnosis of perforation in the early stage—i.e., for the first few hours after it has occurred: (1) rigidity, (2) tenderness, (3) presence of fluid, and (4) free gas in the peritoneum; and to these should be added, of course, the pain and signs of collapse. But before considering them and their significance in greater detail I will take you a little further with our supposititious case.

We will suppose that, for some good reason, either that you have been unable to attend immediately to the first summons or that you have sent for assistance, or that you are called in consultation upon the case several hours after the catastrophe—what will you probably find? A period of calm after the storm. The patient looking fairly comfortable, the pulse a little faster and small but not alarming, the temperature slightly above the normal, cessation of the vomiting, the agonising pain gone, and the patient expressing himself as feeling fairly comfortable and in a fair way to recovery. You examine the abdomen and what do you find? 1. Rigidity giving place to distension, but still there is immobility in respiration. 2 Tenderness still present, though in less degree and not so general. In an appendix case the localisation of the pain at this stage may be an invaluable guide. 3. Free fluid probably increased, though you must not forget that great distension of the intestines may obliterate the percussion dulness in the flanks by displacing the fluid. 4. You will probably find that neither fæces nor wind have passed per rectum. I have myself been deceived by this apparent extraordinary amelioration of the symptoms, and I have seen men of far greater experience than I can claim thoroughly taken in by it. But this period is the golden opportunity for operating, or even for removing a patient to a hospital or place suitable for operating in; and, while I personally should not deliberately wait for it as the elective period for operation, I should not, having made my diagnosis at an earlier stage, or seeing the case for the first time in this stage, when a competent man had earlier diagnosed perforation—I should not, I repeat, refuse to operate because the patient had apparently become so much better.

In the foregoing paragraph I have twice used the word "apparent" in connexion with the improved condition of our patient, and I think that if we spend a few minutes in considering the pathology of the symptoms we shall better see why the improvement is rather apparent than real. Let us first take the most obvious and to the patient most urgent, symptom, pain. What causes it? Do you at once exclaim, "Why of course the presence of foreign matter in the peritoneum"? To a certain extent I agree. I can well understand and realise that acid gastric juice and digestive ferments, especially when to them are added portions of solid food, would be an instantaneous cause of most terrible pain to the sensitive peritoneum. But how about the warm, creamy pus from a ruptured pyosalpinx? There is not at first sight anything so instantaneously pain-producing in this. It will in a short time produce peritonitis by inoculation with saprophytic germs, but the pain is instantaneous and severe; it suddenly doubles a man up when he is walking in the street, and he will describe the sensation of "something giving way in his inside." Again, the pain diminishes after the first severe bout, but the food particles are not absorbed. "They are diluted by the outpoured peritoneal fluid," you say. This will hold good as an argument when dealing with the gastric contents but not for the septic pus. Dilution will only serve to disseminate the latter. Time will not allow me to elaborate this interesting point, but I will just say that I think that the first shock of the irritating fluid from stomach or abscess causes a vaso-motor paralysis—immediate or spreading, dilatation of the peritoneal bloodvessels, and roughening from hyperæmia of the hitherto smooth endothelial surface, and that the pain is caused mainly by irregular peristalsis of the intestines in these altered conditions. Septic intoxication of the local nerve ganglia, assisted oftentimes by an opiate, then arises, and the period of rest supervenes because the peristalsis ceases. In other words, the intestines become paralysed; and the resulting inability to pass wind or fæces gives rise to a condition of obstruction. I should like to note in passing that this is often a cause of a mistake in diagnosis, because all medical men do not realise that peritonitis is a cause of paralysis of the bowel and so of obstruction. The bowel being paralysed is unable to carry on its peristaltic action, and with the cessation of movement you get cessation of pain. If this were all one would be inclined to say "very good" but the effect of the paralysis does not stop here. The bowel having lost its peristaltic movements has also lost its contractile power, and it stretches with the pressure of gases inside it, and so you get the condition of distension. Before this increasing distension the rigidity rapidly yields; if it did not so yield I suppose that the pain of distension would be considerable, and the displacement of the heart by the accumulating gases in the intestine might be rapidly fatal.

In such a case as I have pictured I have no hesitation in saying that the first thing you must do is to make your diagnosis, and then to give an anodyne. In perforating gastric ulcer you must give a hypodermic injection of morphia—a quarter of a grain is usually sufficient—to relieve the pain, to counteract shock, and to assist the patient as speedily as may be to the second stage. But in the meantime you must not be idle, you must prepare for the operation which is imperatively demanded. Send for your operator or your assistant, for your chloroformist and for a nurse, if the operation is to be performed at the patient's house. If such a course is inadvisable or impracticable you must arrange to have your patient removed as comfortably and as speedily as possible to a suitable place.

The case which I have just sketched is of the perforating gastric ulcer type, but there is another form of perforative peritonitis which is usually associated with the appendix and in which it is by no means so easy to come to a decision. The term "perforative" is used in the potential or future sense rather than in the past or perfect, and signifies threatening perforation. These cases have usually a history which is of great assistance in localising the seat of mischief, but as the appendix is usually the offending organ we will take such a case as a type. The illness begins with a well-marked sudden and severe pain, not by any means always referred to the right iliac fossa. It is quite as common in my experience for the pain to begin round the umbilicus, and so you may jump to a hasty conclusion that it is a case of intestinal colic. Again, the pain may be at the splenic flexure of the colon—a common place for "windy spasms" in dyspeptic, tea-drinking women. The symptoms may not be very severe to begin with and may develop more slowly, taking, it may be, some hours to arrive at their maximum. The pain will increase to the point of severity and you get the collapse. The pulse may be as bad as in the last case which we considered, but it may be only rather quicker and smaller than normal. The special abdominal signs—rigidity, absence of respiratory movements, and tenderness—will be present, and I need hardly say that in appendix cases you usually get, sooner or later, a particularly tender spot midway between the umbilicus and the iliac crest. Important evidence as to tenderness localised in the right iliac fossa is obtainable from a rectal examination, which should always, I think, be made in these cases. So far the case resembles an ordinary appendicitis, but let us suppose that the symptoms are severe all round, so that we have good reason to fear the formation of abscess. In these cases you also get the second stage of rest, and in proportion as the first stage has been mild you will be likely to be deceived by the amelioration of symptoms at this time. Careful attention to the condition of the abdomen alone can save you from mistake. Here the temperature is of great importance, because the absorption of pus or of its toxins by the cellular tissue in and around the *appendix causes* a well-marked rise of temperature.

We have arrived, then, at suspecting the formation of pus in connexion with a perforated appendix. We only suspect pus. We have not yet got beyond the point where we can say definitely that the appendix is the seat of trouble. What we want to know is whether the appendix has perforated. Then, if so, whether it has perforated in a situation where adhesions will rapidly form and shut off the general peritoneal cavity, or thirdly, whether it has given way in a position which will speedily overwhelm the patient with a general septic peritonitis. These are points of supreme importance, because, in the first case, if no perforation has occurred and abscess is unlikely, it is better to let the attack subside and to remove the appendix when things have *quieted down. Secondly, if the appendix is in its* usual position, behind or to the outer side of the cæcum, an abscess may form, but local peritonitis will probably shut off and guard the general cavity from the dire effects of the foul pus. To find such an abscess in the early stage of its formation is by no means easy, and in seeking it one can easily destroy nature's barrier, and, with a small abscess of, say, two drachms in amount disperse it over the peritoneum in endeavouring to discover it; whereas if we allow it to increase to a considerable size we shall be able easily and satisfactorily to evacuate it. The third consideration which I have in my mind is fortunately the least common and is that in which the appendix runs inwards towards the middle line of the abdomen or over the pelvis. A long appendix one can picture hanging over the pelvis and almost dropping pus into the pelvic peritoneum.

Now how are we to decide in a given case as to which of these conditions is probably before us? I think that there are three things upon which we may rely with some sense of security. They are; (1) the condition of the patient—the pulse, the temperature, and the aspect; (2) the condition of the abdomen; and (3) the presence or absence of a swelling. We will leave the condition of the patient for a minute while *we briefly consider the second and third signs.*

The condition of the abdomen.—This has to be considered from the point of view as to whether distension has come on, and whether the peritonitis causing it is general or local. The former we can see at a glance, and we will suppose that the stage of rigidity has passed into that of distension. We shall lightly percuss the flanks to see whether there is dulness—i.e., fluid or exudation—and shall very likely find that there is impaired resonance if not actual dulness in the right flank from exudation, and that the left is tympanitic If the left flank is also dull we shall know that the peritonitis is rather more than a local one and that fluid is accumulating in the general cavity—though I think that in appendix cases this is a rare condition Because distension is general over the abdomen we must not necessarily infer that the peritonitis is also general or that the paralysis of the intestine is complete. We shall very likely find that on the left side pressure can be made with little or no pain, and we can infer from that that the peritonitis is not universal. Paralytic distension of the bowel is usually extended far beyond the site of the lesion or local peritonitis which causes it If we hear gurgling or see peristaltic movements we shall know that paralysis in not complete, but we can do more than this. We can pass a rectal tube and see whether flatus escapes, or we can give a turpentine enema which may also serve the useful purpose of clearing out the rectum and sigmoid flexure. If we find then that contractile power is left in the bowel we infer that the general abdominal condition is not very bad at present.

The presence of a swelling in the right iliac fossa.—What constitutes the swelling in a case of appendicitis? First, the persistent rigidity of the muscles over an inflamed spot—rigidity which does not yield as readily or as rapidly as that over the rest of the abdomen. Deeper you have œdema of the transversalis fascia, of the omentum, and of the cæcum and adjoining intestine with matting together thereof. Indeed, all the cellular tissue of all the structures involved in the inflammation is infiltrated with lymph and serum, and being thus hardened and fixed gives rise to a palpable swelling. Now this swelling is a good sign, for it shows that nature is making a good fight and is putting barriers between the poisonous pus and the general peritoneal cavity. In a very few hours, probably before pus will have had time to form, nature will have made the passage to the abdomen impregnable to its assaults. As a rule, then, the presence of a definite tumour without distinct signs of pus in it relieves our minds of pressing anxiety. We must assiduously watch the pulse and temperature, in four-hourly observations if such can be arranged for, because although we are tolerably (though not entirely) free from the danger of pus entering the peritoneal cavity, we have to recollect that the pus in these cases is very fœtid and very virulent and may soon destroy not only the appendix (that is not much loss) but even adjacent bowel, as I have seen in more than one case which has been left too long unopened.

The condition of the patient.—This is the principal and important point upon which we have to form an opinion based almost entirely upon our own experience. The second and third signs are purely objective and can be seen or discovered with ordinary care by the merest tyro, but experience and ripe judgment are needed to *decide whether the patient is suffering from a septic peri*tonitis which will very soon kill him, or whether he has a local condition which he can easily last through for some days and finally recover from when the appendicitis resolves or the local abscess is opened. It is most difficult to convey to others the points, minutely balanced *pro* and *con*, with the reservations which one has in one's own mind in considering such a case, and were I to attempt the task I should, I fear, only obscure the subject of our discussion. I will, therefore, put it broadly into two types, the sthenic and asthenic.

The sthenic you can afford to watch. The patient's face is possibly flushed, he is alert, and gives you the impression of reserved strength, but he has no delirium. Delirium in surgery is a danger-signal of grave significance. The pulse may be fast, and even small, from the contracted artery of peritonitis, but it is in accord with the temperature, which is high, say, 103° or 104° F, and has power and tension. In such a case you can, I say, afford to wait, especially if the distension is not alarming and you can feel a distinct swelling. But you must have a very clear idea as to what you are waiting for You are waiting for one of two things, either the resolution of the inflammation without abscess or the *earliest possible moment* when you can safely evacuate the pus, the presence of which you have diagnosed and the potency of which for ill you dread—pus which you have diagnosed either from the temperature chart, from a rigor, from a local œdema of the skin, or from the presence of fluctuation in the swelling I say the earliest possible moment, because I recently saw a case most severe in all its stages in which the patient and his friends absolutely refused me permission *to operate in the earlier stages and* I did not consider it a case to press. I diagnosed and localised the abscess and said that it should be evacuated; indeed, I offered to see the case the next day and to do the operation. Early the next morning the abscess burst into the peritoneal cavity and the man died The diagnosis and course of the case were verified post mortem. Now, I believe that if I had insisted more strongly upon the immediate danger that the abscess was to *his life I might have over*come their repugnance to the operation which I knew and declared to be necessary. But it seemed to me to be so certain that it would be soon pointing over the iliac crest that the idea of its finding its way into the peritoneum hardly crossed my mind I hope that I have learned that lesson. One word more on the sthenic type. If you are watching such a case and the temperature suddenly falls without a corresponding improvement in the pulse you should decide on immediate operation, as it probably indicates a sloughing of the appendix at least and may mean something more serious.

The asthenic type is the last that we have to consider and is the most dangerous as well as the most difficult to decide upon. I am not referring to cases which are moribund when you first see them—cases in which pain has been deadened by repeated opiates and which have been allowed to drift through the first and second stages until the patients are all but dead from septicæmia and with probably multiple septic abscesses in the liver; cases in which blue lips and fingers with a thready, rapid, or uncountable pulse tell that dissolution is imminent. Operation can do no good in such a case; it will only hasten the inevitable termination. In such a case you can only try with heart-stimulants, strychnine, brandy, and the like to restore the circulation to a point at which you might be justified in operating; but if, as is probable, your efforts in this direction fail you must not discredit surgery by doing a useless operation. In such a condition I doubt whether one is justified—nay, I do not think that one is—in subjecting the patient even to the examination necessary to found a diagnosis upon. No; the type of which I speak is that in which there is evidently profound disturbance. The complexion is pale or sallow, the pulse is rapid, small, and compressible, and the temperature is only slightly raised—not at all the temperature which one likes to see with the quick pulse. Or, again, the pulse and the temperature may neither of them be much increased, but still the patient, who has the history of appendix trouble and the abdomen of peritonitis, is evidently suffering from profound septic poisoning. In such a case you at once look for the swelling, and if you find it, you may conclude—particularly if it is known to have been present for a day or two, and the patient is at the end of the first week of his disease—that there is an abscess which is doing damage, that the appendix has sloughed or is sloughing, and that the abscess is dangerously near to perforating, even if it has not already done so, the peritoneal cavity. If you come to this conclusion you will of course arrange for immediate operation. But, you may not always have the help of finding the swelling, either because it is so slight as to be unrecognisable or the abdominal distension is so great as to mask it. I want you clearly to understand the situation. A patient with a history of appendicitis with symptoms of severe septicæmia of a low type evidently dangerously ill, the abdomen swollen but not very tender, and no swelling in the right iliac fossa that you can detect. What is to be done? Well, first, if it is a woman make quite sure that it is not pelvic peritonitis arising from pelvic cellulitis. I have quite recently seen a case, and can recall another, in which a vaginal examination saved the situation so far as I was concerned, and the patients went through their attacks satisfactorily. Having satisfied yourself that this is not present I think that an operation should be done to discover whether there is pus in the abdomen in connexion with the appendix or Fallopian tube. The operation is difficult and the prognosis is doubtful, but the risk of the operation is less than that of letting the patient run on to almost certain death. These cases are fortunately rare and are usually connected with an appendix which is tucked away behind the cæcum or colon or to the inner side of them and are due to the insufficient protection of the abdominal cavity by adhesions, so that a larger portion of the peritoneum is exposed to septic infection than is compatible with life.

I have indicated, I think, the conditions in which I should operate, but before concluding I should like to say a word about the propriety of refraining from operating during the condition of profound shock which often obtains at the onset of these cases. The condition is purely one of shock, because the history will tell you that the patient has only been ill for an hour or two. If I find a patient in this condition of shock and with a very rapid pulse—130 and upwards—I prefer not to add to the shock of the disease by the shock of an operation. The patient has, in my opinion, a better chance of recovery if you first rally him with strychnine, brandy, and a dose of opium. It is bad surgery to wait in a case of perforated gastric ulcer unless you have strong reasons for doing so, and I can think of no other reason than this that would make me delay. You can, as I have said earlier, utilise the time of waiting by preparing for the operation, and probably by the time that you have everything ready the pulse will have improved sufficiently for you to feel happy in carrying out the treatment that is so urgently needed.

A word in conclusion about opiates. To relieve the agonising pain at the beginning of the attack—and we must remember that the pain enhances the shock—an opiate is usually necessary; but if persisted with—if, that is to say, we keep the patient under the influence of opium—we obscure the diagnosis and increase the distension. I dislike morphia for the latter reason, I always think that it is more of a bowel paralyser than opium. If possible make your diagnosis before you give an opiate; if you cannot, then give the opiate and see the patient again in from four to six hours (in the case of suspected gastric perforation four hours is too long) and again try your best to make sure of the seat of trouble. You will then be able to ascertain for yourself whether more opium is necessary, and, if pain demands it, you can order another dose; but you will have had the advantage of observing the developed abdominal condition when the patient has more or less thrown off the effect of your first dose. You will be doing the right thing by your patient and yourself if you insist on no opiate being given, except in your presence, until you have arrived at your diagnosis.

Exeter.

RECURRING ATTACKS OF CATALEPSY ALTERNATING WITH VIOLENT MENTAL EXCITEMENT.

BY W. G. STONE, M.A., M.D. OXON., F.R.C.S. ENG.

THE patient whose symptoms are here described has been known to me since Nov. 15th, 1900. She is a tall, thin woman, aged 27 years, married, but without children. She consulted me with regard to intense headache, from which she had been suffering for the two previous nights, the pain being situated in the supra-orbital and occipital regions. She told me that it came on about 3 A.M., that she was sick two or three hours later, and that she was free from pain but exhausted by 10 A.M. She had had one similar attack about six weeks earlier. She also mentioned at this time that she was subject to temporary attacks of dimness of vision and that she had noticed the great size of the pupils at such times. There were no symptoms suggestive of increased tension and no ocular error could be detected at the time of her visit.

With regard to her family history, her mother, who is known to me, is subject to very violent attacks of temper, so severe, indeed, as to make her home almost uninhabitable to her husband and children. In her ordinary life she is quiet and pleasant, but when excited she loses all control of herself, using the most abusive language, and seeming for the time to be really dangerous. She has, however, never suffered from definite delusions of any kind, nor has she shown much evidence of hysteria of a milder form. In other members of the family there is no record of nervous troubles that I can discover.

As to the personal history, the daughter is usually of a bright and lively disposition; she is fond of amusement and is very happy in her home life. She is not liable to sudden fits of crying or any of the milder hysterical outbreaks. Her first mental symptoms appeared after her marriage, which occurred three years ago. One night, while staying at Ventnor for her honeymoon, she became violently and ungovernably excited and remained in this condition for three hours. Since that time the excitement had been apt to recur at or after the menstrual periods, and I am told that at such times she "wandered in her mind"; she had been heard by her husband to mutter "I must do it," and had twice been seen by him "looking for a razor." She also had spoken of a wish to destroy herself. The menstrual loss was excessive, lasting for fully a week; and it had usually been accompanied on the second day by great pain as well as by vomiting. She obtained considerable temporary benefit from a prolonged course of ergot in 1898, and the decrease of menorrhagia was accompanied by a decrease of mental symptoms. Six months after her marriage she had a prolonged febrile illness which was diagnosed with some hesitation as enteric fever; in this the mental symptoms were very pronounced and there was great insomnia.

When first seen by me she was anæmic and very thin but without positive signs of disease except the menorrhagia already mentioned. The temperature was normal; the tongue was fairly clear and moist, though she had much constipation. The heart sounds were normal; the pulse was small and rather tense but regular; the lungs were normal; sensation, muscular power, smell, taste, and hearing were unaffected. The knee-jerks were present. There were no tremors and no giddiness; the pupils reacted to light and accommodation; the movements of the eyeballs were normal. There were no ovarian tenderness and no tenderness along the spine. The urine was normal. The appetite was poor, especially during the daytime, when she took her meals alone. On Nov. 24th she again came to me complaining of headache. She was at the end of a menstrual period, during the whole of which her headache had persisted; the period had lasted eight days, but the loss had been less than usual. She seemed to improve for a day or two and the catamenia ceased, but a season of intense mental excitement then ensued. It lasted for two days and for that time sleep was quite absent. She could converse and argue with those about her but did not recognise them. On recovering two days later she found that she had no recollection of the interim. "She had lost two whole days," as she said. I saw her several times while in this condition. On the first occasion she was excited when I arrived—struggling violently to get out of bed, tearing her hair, and striking her head with her hands or knocking them violently against the rails at the head of the bed. Then she would fall back, seemingly exhausted, but suddenly would leave this condition to sing, in the manner of Ophelia, little snatches of song She did not know me at all and was indignant that her medical attendant had not come as he promised. I said that I was he, but she replied, "I know you're not: he would not have been so rude." Then she added, spasmodically: "Your hair's all rough; you might have brushed your hair"; and then began struggling violently to get out of bed. But she had no other definite delusions; she did not, at any rate, imagine that she saw or heard more than the rest of us. All this time she complained of throbbing pain on the top of her head. An ice-bag gave some relief to it, but still she got no sleep. Bromide of potassium with chloral hydrate were given in the evening without effect; also on another occasion caffeine and phenacetin, and a third time inhalation of amyl nitrite. Some benefit was apparently derived from a mixture containing valerian with spiritus ætheris co. During the two days of excitement she was constipated, with a dry, furred tongue, and very thirsty, but with a normal temperature. Nothing excited her more than the proposal to have a nurse in attendance, and she threatened to do her serious bodily harm "if one of those frillicaps was brought." In two days' time the excitement subsided and she had some very good sleep, awaking, as has been mentioned, without any recollection of the last 48 hours. This was on Nov. 30th. She improved during the next fortnight and kept her bed during the whole of the next monthly period. This passed without violent excitement. There was some pain, but less than usual; the period lasted a little over a week, and 18 diapers were used. One day she passed a membranous cast of the uterine cavity and said that the same thing had also occurred some months previously. As this suggested a cause for her dysmenorrhœa, menorrhagia, and sterility, a vaginal examination was advised when the period had been followed *by a fortnight of fair health. It was then that a definite* cataleptic condition was first observed, but there was reason to suspect that the faints reported by her friends during the two days of excitement might have been in reality cataleptic seizures.

The vaginal examination took place on Jan. 1st, 1901. She had felt nervous on the morning of that day and had taken a dose of the valerian mixture of her own accord. A bimanual examination was made in the dorsal position with only moderate struggling, but on the attempt to introduce a speculum she became violently excited and it was at once evident that the attempt must be abandoned. She tore her hair, struggled terrifically, and cried out, "You have made me mad," "I am a mad woman," shrieking again and again. Some valerian was administered with difficulty and then the cheek was sharply slapped with a wet towel. Upon this she fell back and her friends said that she "had fainted again" She lay unconscious, but with her eyes open, fixed, and slightly turned upwards. She was slightly pale, her mouth was half opened, she breathed quietly, but rather shallowly, and the pulse was soft but not weak, with a rate of about 80; the reflexes were not examined. The limbs were found to be in a typical condition of flexibilitas cerea. There was scarcely any resistance or stiffness when the joints were moved, but the limbs remained just as they were placed, though they felt so plastic and unresisting that I thought they would drop at once when let go. I first raised each arm and left it in this posture; then I flexed all the joints, shoulder, elbow, wrist, and fingers, and they stayed flexed; then I straightened each joint separately; and lastly put the arm so that it formed an angle of 30° with the surface of the bed, when gravity would have every advantage over the supporting muscles. In no case was there any feeling of rigidity, but in every case the arm stayed as it was placed. The same was then found to be true of all the joints of each leg, and lastly, I put the patient in a sitting position and she remained sitting upright, while the head was bent first to the right, then to the left, then right back so that the face looked towards the ceiling, and finally bowed forward. On each occasion the forced position was maintained by the patient's muscles, though she remained completely unconscious. After about seven minutes the cataleptic state was succeeded by a period of renewed excitement. She again struggled maniacally, and then would laugh or scream or sing short snatches of song. This ceased as before on the cheek being slapped repeatedly with a wet towel, but only to be followed by another shorter cataleptic attack similar to the former one. As this passed away she gradually regained her natural consciousness, though still showing occasional tendency to excitement. In the evening she was quite herself and remembered little of what had occurred. She regretted that the examination had been incomplete and a few days later decided to submit to examination under an anæsthetic. This was accomplished shortly after the next menstrual period. Gas and ether were administered; the uterus was dilated and curetted; and, under careful nursing, the time following the return of consciousness was passed without any hysterical manifestation. She has since had two normal periods and is now gaining strength and weight, suffering but slightly from headache and quite free from any form of violent nervous excitement.

Denmark-hill, S E

ON THE CAUSATION AND TREATMENT OF PROFUSE EPISTAXIS IN PEOPLE BEYOND MIDDLE AGE.

BY GEORGE COATES, M.A , M.D. OXON., M.R C S ENG.

I HAVE had a very interesting series of five cases of profuse epistaxis not caused by a blow or injury but coming on without any apparent cause in adults aged 50 years and upwards, all of whom I have known and watched for several years both before and after the attack, and in whom I have been able to trace the series of events which caused and followed it. The attacks have been sudden in their onset, and profuse, generally lasting from half an hour to an hour or more, and tending to recur for several days. The cases are briefly as follows:—

CASE 1.—The patient was a gouty man. He had had a severe attack of epistaxis 17 years ago, which was finally stopped by plugging the posterior nares in the usual manner. At the same time he developed cardiac disease, i e., well-marked mitral regurgitation. He died 15 years later, aged 82 years, from bronchitis and pneumonia. There was some chronic nephritis.

CASE 2.—The patient was a woman, aged 52 years. She had had profuse epistaxis seven years ago, which also was finally stopped by plugging the posterior nares. She developed mitral regurgitation at the same time. She is now alive and well.

CASE 3.—The patient was a man, aged 68 years. He had epistaxis four years ago. He developed aortic regurgitation at the same time. He was treated with blue pill and a mixture of sulphate of quinine and sulphate of magnesia and rest in bed. Plugging was not necessary.

CASE 4.—The patient *in this case was a woman, aged 64* years, who had suffered for at least 10 years from high arterial tension.

CASE 5.—The patient was a woman, aged 68 years, who had suffered for several years from high arterial tension due to arterio-capillary fibrosis and from contracted granular kidney.

With the exception of the patient in Case 1 all the others are now alive. In Case 4 and Case 5 the patients did not develop any valvular lesion. The epistaxis in both of these followed exposure to cold when they were very tired; they both had over-exerted themselves for many days and then got thoroughly chilled In both, the epistaxis was cured by administering nitro-glycerine and tincture of strophanthus.

In all these cases the sequence of events which led up to the epistaxis was essentially the same, namely:—

(*a*) Long-continued high arterial pressure. (*b*) Some sudden cardiac failure. In Cases 1, 2, and 3 the epistaxis arose from the giving way of a valve. In Case 4 and Case 5 it arose from loss of power of the cardiac wall. (*c*) Over-filling of the whole venous system, the weakened heart not being able sufficiently to empty the engorged veins against the high pressure in the arterial system due to contracted arterioles. (*d*) Leakage from an over-filled vein. In Cases 1, 2, and 3, in which the patients all had a good amount of muscular strength and vigour, the heart had gone on working against this high pressure until a valve, aortic or mitral, gave way. This, of course, diminished the efficacy of the heart as a pump but did not diminish the contraction of the arterioles. Hence followed a sudden change in the circulation of the blood and an increase of blood-pressure in the veins to such an extent that nature gave relief by a copious epistaxis. Although the presence of the valvular murmur was noted at the time and I was surprised to find it as a new feature in each case, yet it was not recognised that the alteration in the circulation which produced the murmur was the cause of the epistaxis. In Case 4 and Case 5 there was not enough vigour of constitution in the patients for the heart to be sufficiently strong to raise the arterial pressure high enough to cause valvular leakage. In them, however, the same state of venous engorgement was produced in the following manner. They had both over-exerted themselves and felt very tired for some days, then when exposure to cold constricted their superficial vessels such a sudden increase of work was thrown on the heart that the tired muscle was no longer able to do its work efficiently. Here again the veins became over-filled and epistaxis occurred. Both these last cases were caused by the same spell of cold weather and various remedies as suggested in the various text-books were tried with little result. When seeing the patient in Case 4 the thought occurred, Why not try to relax the arteries and strengthen the heart so as to get the veins emptied naturally? Nitro-glycerine was given and was perfectly successful; as soon as the smaller arteries were sufficiently dilated the bleeding stopped. In Case 5, a short time later, the same treatment was adopted and the same result followed. The patients were both kept slightly under the influence of nitro-glycerine for some days and tincture of strophanthus was given as well. A few weeks ago No. 2 was in a poor state of health and began to suffer again from epistaxis. She was at once put on nitro-glycerine and small doses of strychnine, with the result that the epistaxis ceased and did not recur. These cases, taken together, form a suggestive series and appear to lead to an obvious conclusion and I think that the result of the treatment in Cases 2, 4, and 5 shows that the theory is correct.

There has been the difference in the subsequent history of these people that one would expect. In Cases 1, 2, and 3 the patients had sufficient vigour for the muscular wall of the heart to hypertrophy until it became able to do its work. In these the circulation resumed its equilibrium and they have had either no further attacks of epistaxis or only very slight ones. In Case 5, where the patient has been suffering from ill-health for years and in whom there is no cardiac hypertrophy, any exposure to cold is apt to bring on epistaxis, but she can always stop it by taking a one-hundredth of a grain nitro-glycerine tabloid. The patient in Case 4 is worth noting as a very anæmic old lady. In her case the epistaxis was certainly not caused by plethora but only by a faulty distribution of the blood. I do not wish in the least to assert that all cases of epistaxis in the aged are due to the same cause, but only that there is a well-marked group in which profuse epistaxis is an outward and visible sign of sudden temporary loss of power of the heart. In these cases the hæmorrhage is purely passive and it is exactly analogous to the attacks of hæmorrhage in elderly persons which may come from the lungs in cases of a suddenly rising mitral disease, from the stomach if the heart should fail in cases of cirrhosis of the liver, or from the uterus (as menorrhagia) in cases of mitral regurgitation, &c.

Here the questions naturally arise, Why should only some people with this condition of circulation suffer from epistaxis? Why should the block not show itself rather by pulmonary symptoms than by hæmorrhage from the nose? The only answer is that in some cases pulmonary symptoms do occur in apparently similar conditions. Of course the hæmorrhage occurs from the relatively weakest point and it is probable that the venous sinuses in the noses of these sufferers from epistaxis have very thin walls. Another possibility is that the question, whether lung trouble arises or not under these conditions, depends on the relative strength of the walls of the two ventricles. If the weakened left ventricle be still able to pump out of the lungs as much blood as the right ventricle can pump into them, naturally no pulmonary congestion can exist, and the block in the circulation must be behind the heart. If, on the other hand, the left ventricle be relatively weaker than the right the lungs become congested with blood, and according to the degree of congestion we may get hæmoptysis, or more or less œdema of lungs, or the condition where the physical signs are those of a bronchitis mainly basic but in which the expectoration is a tenacious glairy fluid, which may be transparent or may be coloured with blood, its hue varying from a light pink or, in the graver cases, to prune-juice. Or we may get symptoms of asthma of varying intensity and this form of asthma is curable also by nitro-glycerine.

The most scientific and satisfactory treatment of these cases of epistaxis, and by analogy of the other forms of passive venous hæmorrhage, is to empty the over-filled veins. As long as they are enormously distended with blood the hæmorrhage must continue unless direct mechanical means are used, and if one nostril be plugged the epistaxis is apt to start from the other. If, on the contrary, we can relax the walls of the arteries and help the enfeebled heart to do its work, it will soon empty the over-filled veins. But, as a rule, this cannot be done by giving heart tonics at first. The heart has been doing its utmost, it has only failed because it has been overworked, and giving a tonic is like spurring a jaded horse. We must bear in mind that in this class of cases the immediate treatment must be directed to the capillaries and small arteries, as the real cause of the epistaxis lies there, not in the nose. Nitro-glycerine is quite effective, nitrite of amyl might be more so, but one of the more quickly acting nitrites should be used at first; afterwards one of the more slowly acting as erythrol tetranitrite or possibly even thyroid tabloids might do as well. When the capillaries and arterioles are dilated and pervious then comes the time for strychnine or strophanthus. Of course each patient must be considered individually, and there are other ways of keeping down excessive blood-pressure and strengthening a weak heart. In spite of everything plugging may have to be resorted to in some cases, but in most of them the hæmorrhage can be stopped without resorting to this procedure, which is always most uncomfortable to the patient and sometimes even dangerous.

Finally, by recognising profuse epistaxis as a symptom of a sudden though mostly temporary heart-failure, there is no danger of commencing valvular disease being overlooked and the patient being considered as one who only requires a little surgical treatment. In some cases it is possible that the alteration in the circulation causing the epistaxis may also cause cerebral symptoms, but here, again, the cerebral symptoms are mostly not the cause or the result of the epistaxis but only the result of the circulatory conditions leading to the epistaxis.

Brechin-place, S.W.

A CASE OF RECOVERY AFTER OPERATION FOR DIFFUSE PERITONITIS FROM PERFORATION OF THE APPENDIX.[1]

By CHARLES A. MORTON, F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, BRISTOL; SURGEON TO THE BRISTOL GENERAL HOSPITAL AND TO THE BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.

I THINK it would be well at once to define the nature of the case which I now report, and have called one of "diffuse peritonitis." Many such cases have been recorded as recoveries from general peritonitis, but when the records are read it is obvious that, although the infection was widespread, there was no evidence at the operation that the disease involved the whole, or in some cases even the greater part, of the peritoneal cavity. These cases are examples of an infection of considerable extent, an infection far beyond the limits of a localised collection of pus around the appendix, but they are not cases of general infection. To this class my own case, I believe, belongs. I know from what we found at the operation that the infection was widespread, but I think that it is doubtful if it involved the upper part of the peritoneal cavity. The recovery of the patient is, I think, evidence that it probably did not do so. When the great disappointment which is often experienced after trying to save a case of widespread infection of the peritoneal cavity, from perforation or gangrene of the appendix, by operation, is borne in mind, it seems to me worth while recording successful cases, as an encouragement to operate if the opportunity presents itself early enough. This case appears to me to teach a lesson well worth learning, and that is that operation in recurrent cases cannot always safely be postponed until the quiescent period. We cannot feel assured that because a patient has had several attacks of appendicitis the appendix must therefore be safely buried in adhesions and the risk of infection of the surrounding peritoneum almost *nil*. My case is an instance of a most serious infection of the peritoneal cavity in the fourth attack of appendicitis, and I have collected a considerable number of cases of such serious infection in recurrent attacks. The case is also of interest as an illustration of the fact that serious infection of the peritoneum may be present and yet the general condition of the patient be remarkably good. These are just the cases in which an early operation is attended with the best results, for the patient is saved from the gravest possible danger and the operation is performed at a time when his strength is well equal to it.

---

[1] A paper read before the Bristol Medico-Chirurgical Society on March 14th, 1901.

The patient was a man, aged 44 years. He woke up on the morning of Dec. 4th, 1900, with some slight abdominal discomfort, and during a journey of several hours to Bristol in the morning the pain became severe. It was present in the right iliac fossa, but also darted up and down the right side of the abdomen in the line of the right rectus muscle. He did not vomit. He was seen by Dr. Barrett Roue in the afternoon and I saw him with Dr. Roue in the evening. His pain had then been a little relieved by opium. His pulse was only 80 and the temperature was under 100° F. The abdomen was very little if at all distended, but the right side was rigid. It was only tender over a small area just inside the right anterior superior spine. There was a normal amount of abdominal breathing. No swelling was present. There was a history of three previous attacks, one in July, another in August, and a third in October. The diagnosis of appendicitis seemed clear and as there had been three previous attacks I thought we might safely watch the case. On the following day (the 5th) the patient complained of pain in a very unusual position—the left side of the perineum and in the penis, and he said that it started in the right hypochondriac region and spread down the line of the right rectus muscle into these parts. The abdomen was somewhat distended and also slightly rigid and tender on the left side as well as on the right. He had no vomiting, although he was taking a fair amount of milk. Only one-sixth of a grain of morphia had been given hypodermically on the previous evening. On the next morning (the 6th)—that is, 48 hours from the commencement of the attack—there were more abdominal distension and more general tenderness and the abdominal breathing had disappeared. Although the pulse was only 80 and the temperature was below 100° and the patient showed no sign of prostration I decided to operate as the increasing general distension and tenderness seemed to be unsatisfactory signs. Not that general distension alone is a certain sign of widespread peritoneal infection in these cases, for in some of my cases of appendicitis in which it has been marked the disease was strictly limited to the appendix.

I opened the abdomen over the region of the appendix and found what I have observed in other cases of intraperitoneal suppuration, very marked œdema of the connective tissue just beneath the external oblique aponeurosis. On dividing the peritoneum a very red and distended cæcum presented and from beneath this I evacuated a small collection of pus which was only retained there by the pressure of surrounding distended coils of intestine. I next passed a sponge on a holder down into the true pelvis, and on withdrawing it a large quantity of thick pus escaped from the pelvis, which was then thoroughly sponged out. All the coils of intestine which presented in the wound were very red and had exudation of lymph on them. The appendix was perforated close to its attachment to the cæcum, and I removed it. It was almost free from adhesions. A very long glass drainage-tube was placed in the pelvis, another in the right loin, and a small one against the stump of the appendix, and gauze wicks were placed in the tubes. There was no shock from the operation, but I must say that the condition of the peritoneum was so bad that I did not expect the patient to recover. In spite of my fears, however, he began to improve from the time of the operation; flatus was passed and the abdominal distension slowly subsided. He was fed only by the bowel for the first 48 hours, and occasionally turpentine enemata were given. Only serum drained away from the tubes, but this came in considerable quantity at first, though the quantity soon diminished, and a few days after the operation the glass tubes were changed for rubber ones. He never had very much pain after the operation and had no vomiting at any time during his illness. Ten days after the operation the abdomen was soft and of natural shape and he was taking fish and other kinds of solid food. All the rubber tubes were removed five days after the operation, but on the following day for the first time a little pus was discharged from the drainage-tube track leading to the stump of the appendix. As the discharge continued a very small drainage-tube was inserted into the track and a slight discharge persisted for a fortnight and then the sinus healed. The patient made a satisfactory convalescence and has since remained quite well.

I think the record of this case will show how dangerous a recurrent case of appendicitis may be, and that severe peritoneal infection may be present with a pulse hardly raised above normal, a very slight rise of temperature, and a complete absence of vomiting and of those signs of general prostration which are so frequently associated with septic peritonitis. I hope that by adding one more to the list of recorded successful cases of operation I may give some further encouragement to operate for septic peritonitis if the patient is seen early enough.

Bristol.

THE OPEN-AIR TREATMENT OF PHTHISIS AT HOME:

A SHORT HISTORY OF A CASE.

By F. WHINFIELD BARTLETT, M.R.C.S. ENG.,
L.R.C.P. LOND.

THE patient, aged 38 years, the wife of a baker residing on his business premises in the country, two miles from a small town, had, before coming under my care, been treated by my predecessor for phthisis. During the years 1897, 1898, and 1899, she consulted me on several occasions for attacks of pleurisy on the left side. During the winter months she suffered much from cough and shortness of breath. There were well-marked physical signs of consolidation in the upper lobe of the left lung, with a cavity at the apex. In the intervals between the pleuritic attacks she felt well enough to perform her ordinary household duties and continued to do so until the onset of more acute symptoms in January, 1900. There was no history of tuberculous disease on her father's or her mother's side, but her only child, a boy, aged nine years, had suffered from tuberculous disease of the knee-joint, for which I had amputated through the thigh in September, 1899. He has never developed any pulmonary symptoms.

On Jan. 8th, 1900, I was called to the patient's house and found her in bed. She had been shivering, the pulse and respiration were both very rapid, the temperature was 102° F., and there were much cough and expectoration. These symptoms continued to be very acute for a fortnight, then they gradually remitted until in the first week in February her condition was as follows. The body was considerably wasted (her weight was 89 lb.), her evening temperature averaged 100 6°; there was considerable dyspnœa; respirations were from 30 to 40 per minute; there were severe night-sweats and much cough with expectoration of large quantities of viscid mucus (this had declined from four or five ounces to about two ounces per diem), sometimes muco-purulent and always containing "nummuli" and sometimes streaked with blood. There was much bodily weakness with anorexia and great restlessness and nervous irritability. With regard to physical signs there were marked flattening and deficiency of respiratory movement on the left side; the left clavicular note was quite dull; the percussion note was quite dull at the apex and was markedly impaired over the whole of the remainder of the left lung, front and back; the breath-sounds were cavernous at the left apex with very distinct bronchophony and pectoriloquy and much coarse metallic râle. The breathing became bronchial in the axillary region and faded to a weak respiratory murmur over the base, where also pleuritic friction sounds were to be heard. There were also signs of commencing disease of the right apex. A specimen of the sputum was sent to the Clinical Research Association for examination, and the report was that "tubercle bacilli are present in small numbers."

As the prospect of the patient's recovery seemed to be under ordinary conditions very slight I advised that she should undergo the open-air treatment. To this she and her friends willingly consented, but as residence in a sanatorium was out of the question, I persuaded them, being influenced by the account of a very successful case reported by Mr. T. A. Somerville and Dr. Eugene S. Yonge,[1] to carry out the treatment at home. For this purpose a shepherd's van which happened to be on the premises was moved into the garden at the rear of the house. The side of the van facing south was removed and rebuilt to the height of three feet six inches from the floor, leaving a space of four feet between it and the roof the whole length of the van, provided with shutters for use in stormy weather. A small stove with a flue was placed in the van for the sake of comfort, and the patient then took up her residence there. The season was winter (she commenced the treatment on Feb. 7th) but she spent the whole of the time between breakfast and sunset lying on a couch or sometimes sitting in an easy-chair in this situation with the exception of half an hour for dinner in the middle of the day, when she went in-doors. Whilst in-doors—in her sitting-room in the evening and in her bedroom at night—the window was always kept wide open, a screen being placed between the window and the bed to prevent any draught being felt. Although the other occupants of the house complained of the cold and discomfort she herself felt no inconvenience even in the coldest weather. Occasionally, in very stormy weather she would remain in-doors for a day or two, wind and a damp atmosphere apparently causing laryngeal catarrh, whilst a cold dry air had no such effect. When the weather was favourable she took short walks. She was enjoined to take a liberal diet, but her distaste for food was such that she could never take much meat or solid food of any sort. Her usual daily menu was three pints of milk, one egg, a little bacon (at breakfast), a few thin slices of bread-and-butter, occasionally a little meat and vegetable, and, in the winter months, a plate of oatmeal porridge with milk for supper. During the first three or four months of treatment she took a capsule containing one minim of creasote three times a day. She also used inhalations of terebene several times daily, and frequently took an anodyne cough mixture. I visited the patient twice a week during the first few months of treatment, and afterwards at gradually lengthening intervals. She kept a daily record of her morning and evening temperature and a weekly record of her weight. Within a week or two of her taking up her out-of-door residence her condition began to improve—the cough diminished in frequency and the sputum in amount, the evening temperature fell to below 100°, and she commenced to gain in weight. In the first seven weeks she gained 7 lb.; then her weight remained practically stationary for two months. During this period the evening temperature averaged about one degree above normal. In April she had a slight relapse; the temperature rose to 101° (for a few days it was 102°), there were considerable prostration and nervous irritability, and she was much troubled with laryngeal hoarseness and cough, so that I deemed it advisable that she should remain indoors and in bed. Under the influence of rest and warm inhalations of compound tincture of benzoin the symptoms subsided and in a week or two she was able to resume her out-of-door life. After this, with the exception of a second slight relapse in May, the improvement was gradual but continuous.

The record shows that the fall in temperature and the gain in body-weight proceeded *pari passu*. By the beginning of August the evening temperature had fallen to normal and has never once since risen above it. Her weight at that time had risen to 102 lb.; by the end of the year it had increased to 114 lb., at which it remained at the beginning of February, 1901. The improvement in her condition at this time, 12 months after the commencement of the treatment, is very marked. In place of being a fragile, cachectic woman with sunken cheeks and a hectic flush she is now plump and well-conditioned, with a healthy complexion; in fact, she complains of being uncomfortably stout. Cough and expectoration have almost disappeared—she coughs a few times in the course of the day and occasionally expectorates a little mucus which is never blood-stained. She has had no night-sweats for many months, no hoarseness, and no pleuritic pain. As to the physical signs, there are flattening and deficiency of expansion of the chest-wall on the left side, the percussion note is dull at the apex and impaired at the base, whilst there are still tubular breathing, bronchophony, and pectoriloquy at the apex, and the breath-sounds are weak at the base. The loud metallic râle which was so audible at the apex has disappeared and there is now only a faint crepitus at the extreme end of inspiration, whilst the crepitation at the base is much less in amount and pleuritic friction is absent. The signs of commencing disease of the right apex have disappeared. There is still considerable dyspnœa on exertion, but otherwise she feels quite well. The Clinical Research Association reported of a specimen of sputum examined on Dec. 24th, 1900, "No tubercle bacilli were discovered."

It remains to be added that beyond the fact of its being situated in the country the patient's residence presented no special advantages for the carrying out of the treatment. It is situated in the low-lying valley of a river where mist and fog are very prevalent. On the other hand, the patient and her friends are people of intelligence; they entered into the treatment with zest and carried it out with zeal and thoroughness, and to this, no doubt, the satisfactory result is largely attributable.

Romsey, Hants.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CONCURRENT ERYTHEMA MULTIFORME AND ERYTHEMA NODOSUM.

By Edward McCulloch, M.B., Ch.B. Edin.

Although modern dermatological literature favours the view that erythema nodosum is but one of the many manifestations of erythema exudativum multiforme, sufficient difference of opinion perhaps remains to warrant the consideration of those rare cases where definite erythema nodosum co-exists in the same individual with other undoubted manifestations of erythema multiforme. In the following case the character of the lesions was unquestionable, and the family history has also an interesting bearing on the etiology of the disease.

The patient was a boy, 15 years of age, who came to me on Dec. 31st, 1900, complaining of "lumps on his legs and spots on his face." He had been exposed to rain and had got a wetting a few days previously. Examination of the shins revealed a typical eruption of erythema nodosum, about five nodes being visible on either shin. Each node was of about the size of a small walnut. Their colour was a dusky red and they were tender on pressure. Their margins were ill-defined and they were unassociated with itching or pain. On the middle of the extensor aspect of the left thigh there was one similar node. On the face there were a few small groups of reddish papules; some coalesced to form small raised patches, situated on the infra-orbital regions and just external to both outer canthi. A few papules were also visible on the alæ nasi and adjacent parts of the cheeks. The patient's temperature was 100·5° F. Little general discomfort was felt. I sent him home with directions to go to bed, and ordered 15-grain doses of sodium salicylate every four hours. Next morning the facial eruption had increased in extent, and fresh patches had appeared behind both ears and on the bridge of the nose. Coalescence of some of the original papules had taken place. The papules were moderately hard to the touch and they paled on pressure. They varied in size from a pin's head to a split pea. During the next few days the rash continued to extend, and in a couple of days after the first visit opalescence appeared in some of the papules and others displayed slight vesication, the vesicles being minute and containing a puriform secretion. A certain degree of general swelling was present for a day or two over the area of the eruption, but it rapidly subsided. Papules also appeared on the backs of the hands and fingers and fresh nodes appeared on the shins from day to day for the first week, all gradually passing through the usual succession of chromatic changes. The temperature remained slightly above 100° for six days, with the exception of Jan. 3rd, 1901, when it sank to 99 5°. On the eighth day it was 99 8° and it did not rise above this subsequently. The eruption gradually faded from both face and legs, leaving slight pigmentation behind. This pigmentation was visible on the face as late as the 20th—i.e., for about three weeks—but had disappeared by Jan. 25th.

---

[1] The Lancet, Jan. 20th, 1900, p. 162.

From the above history it will be evident that the nature of the lesions was unmistakeable. The slight rise of temperature, the local appearances, their symmetrical arrangement and their distribution, were all characteristic of erythema multiforme, while the condition of the shins was absolutely typical of erythema nodosum. The case, to my mind, is a very definite demonstration of the identity of erythema nodosum with erythema multiforme. The family history was remarkable. The patient's mother had similar "lumps on the legs" before marriage; his maternal grandmother had had rheumatic fever; an elder sister died at the age of 16 years from rheumatic endocarditis with multiple joint affections; a younger sister was under my care last year with rheumatic fever, and had endocarditis and subsequent signs of mitral stenosis; another sister had had frequent attacks of acute tonsillitis (from which the patient himself has often suffered); and a maternal uncle and three of his children had had rheumatic fever. In contrast to this the patient's father is healthy and has no rheumatic personal or family history. Thus additional support is given, if it be needed, to the view that erythema multiforme is but one of the expressions of rheumatism.

Torpoint, Devonport.

NOTE ON THE TREATMENT OF OTORRHŒA.

By DAVID WILLIAM AITKEN, M.B., C.M. EDIN.

As the method about to be described has proved successful in cases where the alternative is antral perforation it seems well to call the attention of the profession to it Although it is quite prompt in its effects upon acute otorrhœa its benefits are greatest in old-standing cases where the mastoid has become infected. Such cases have lasted for years; there is an abominable discharge, probably with polypoid growths, and if the more threatening head symptoms are not present there are the impaired health, the atonic dyspepsia, the anæmia, and the loss of flesh to denote the dire effects upon the constitution which follow absorption.

The appliances required are a probe, some antiseptic lotion, and some absorbent cotton. The best probe for the purpose which I have seen is that supplied by Messrs. Hockin and Wilson. It has at the end two spiral teeth which, while they hold the wadding firmly, permit of its easy removal by rotating the stem counter clock-wise. The first step is to pour into the ear some of the lotion. Then take as large a plug of wadding as is deemed sufficient when screwed upon the probe to easily fit the meatus. It is now possible to make the probe and ear canal a suction syringe The plug of wadding which forms the piston is gently pushed in and then withdrawn. If it is found to be either too large or too small another can be at once substituted which acts both easily and also fits close enough to force some of the fluid before it. This fluid reaches both the attic and also the mastoid recesses. At any rate, on the first withdrawal sufficient vacuum is produced to allow the lotion to enter the accessory cavities. *It will surprise* anyone who has not carried out this procedure to note how much discharge and débris are brought to the surface even after syringing and swabbing have been efficiently performed. After several repetitions of the manœuvre, the head each time being turned to the opposite side to permit of emptying the meatus, the lotion will well up clean. Now one can get any medicament to the clean surfaces. Begin with chinosol, iodoform, or amyloform in alcohol which, in my experience, is best in the absolute state. It is practically painless in almost all cases and in the exceptions the smarting is but momentary. Its advantages are: (1) it acts promptly upon the polypoid growths; (2) it is a most satisfactory antiseptic; and (3) as it evaporates it leaves a dry surface. This is most important. Many of the cases which progress so unsatisfactorily are those of patients who get a "powder to put in water to syringe the ear with." While the ear is never clean it is kept constantly in a sodden state. When the solution has been poured into the ear the process with the "piston-rod" is repeated several times. Thus the fluid is forced into all the recesses. That this is so is seen by the prompt improvement both in the local condition and also in the constitutional state. Of course, discretion is used as to the nature of the drug selected in the progress of the cure, according to the requirements—stimulant, astringent, &c.—of the case. It is unnecessary to select examples. Suffice it to say that many cases have been treated and that in some the patients have probably been saved from the somewhat serious operation of trephining the mastoid.

It is my belief that this plan, if properly carried out, would greatly diminish the number of antral perforations. In fact, it is as an alternative to that procedure that my device has been matured.

Packington-street, N.

BARIUM WATER IN WEAKNESS OF THE HEART.

By W. BLACK JONES, M.D., B.S. LOND., D.P.H.,

PHYSICIAN TO THE LLANGAMMARCH WELLS SPA.

THE following case, which illustrates others of a similar nature treated at the Llangammarch Wells Spa, may be found to be of interest.

A man, aged 53 years, consulted me for weakness of the heart. He had had influenza seven years previously and since then had suffered from dyspnœa on exertion. He had been losing flesh of late. He was a very thin man, weighing only seven stones. The apex beat of the heart was in the nipple line and the cardiac dulness was increased to a corresponding extent. At the apex a soft systolic murmur was heard which became louder as the right base was approached; over the pulmonary area the second sound was accentuated. The pulse was thin and wiry and the frequency varied from 90 to 100 per minute. Nothing abnormal was observed in the other organs; the urine was unaffected. The patient was advised to drink the Llangammarch barium water, to have a course of barium baths, and to take outdoor exercise in moderation He soon began to improve and after three weeks' treatment he left, feeling considerably better. After an absence of six weeks he reported that he had made greater progress; the pulse was slower, he had practically lost the dyspnœa, and he was able to walk up hill with comparative ease. He was also gaining in weight and was feeling better than he had for years.

Similar to the above case are many in which the heart has been damaged after attacks of influenza. They all receive considerable benefit from the treatment at Llangammarch and often gain considerably in strength after their return home.

Llangammarch Wells, Breconshire.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on April 10th, Mr. Christopher Heath, the President, being in the chair. Ten new members were elected and the deaths of three were reported. The death of a widow was announced. Fresh applications for grants were read from two widows and three orphans and grants amounting to £96 per annum were made and a grant of £25 for the self maintenance of an orphan was given. Applications for continuation of grants were read from 50 widows, 14 orphans and six on the Copeland Fund, and it was resolved that £1218 be given at the July court The following were recommended for election at the annual general meeting to fill vacancies in the list of officers for 1901-2—viz: Dr. Blandford as treasurer, and Mr Sleeman, Mr. Elwin, Sir Hermann Weber, Mr. Stowers, Dr Nix, and Dr. Palmer as directors It was decided to hold the annual general meeting on May 22nd at 5 P.M.

METROPOLITAN HOSPITAL.

TWO CASES OF CONTRACTURE OF THE FLEXORS OF THE FOREARM TREATED BY TENDON LENGTHENING.

(Under the care of Mr. HAROLD L. BARNARD.)

THE treatment of the paralysis which follows the application of splints to a limb was formerly very unsatisfactory, but the operation of tendon-lengthening has proved so very successful that it will certainly be extensively employed. The condition is by no means rare. The mode of production of the paralysis probably varies; some paralyses are due to injury to the muscles, perhaps merely from interference with their blood-supply, while others are certainly produced by the pressure on the nerves of the limb, a traumatic neuritis resulting.

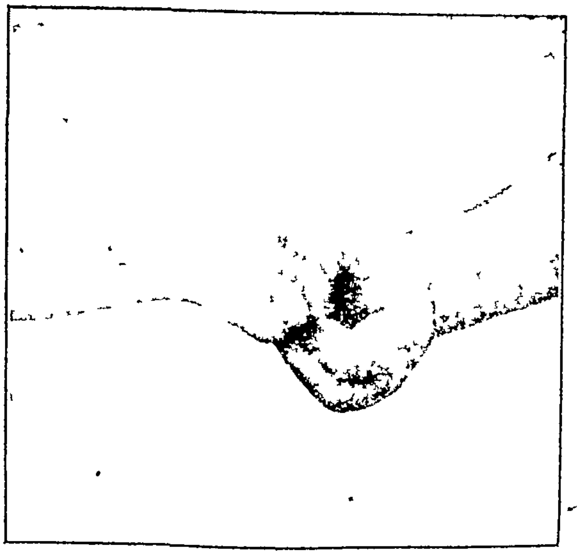
CASE 1.—A little girl, aged three years, was taken to the out-patient department at the Metropolitan Hospital on May 2nd, 1900. On March 16th (six weeks before) she had broken both bones of her right forearm about the middle, and for this anterior and posterior splints were applied and the arm was supported in a sling. She was seen on the next day and complained of no pain. When the splints were readjusted at the end of a week a pressure-sore was found extending for about three inches from the middle of the front of the forearm to the wrist, whilst a smaller one was found on the back of the forearm in its lower part and a still smaller one upon the thenar eminence. The fracture united well and the sores rapidly skinned over and healed. No note was taken at the time whether the child moved her fingers or not. About the middle of April—that is to say, one month after the accident—the fingers and the top joint of the thumb began slowly to flex, and this flexion steadily progressed in spite of massage, the free use of liniments, and the restraint of a splint. It was for this progressive flexion that she was taken to Mr. Barnard six weeks after the accident. The pressure-sores were nearly healed. The position of the hand was that of *main en griffe*. When the wrist was extended the fingers were extended at the metacarpo-phalangeal and flexed completely at the two interphalangeal joints. The last phalanx of the thumb was fully flexed. When the wrist was completely flexed the fingers became extended. There was no definite area of anæsthesia, but voluntary movement was practically lost in the hand and wrist. The operative treatment of the case was delayed for the sound healing of the sores and by a chronic whitlow which appeared on June 27th upon the tip of the right index finger.

On Sept. 10th Mr. Barnard operated, six months after the injury, employing the method instituted by Mr. H. Littlewood and Mr. H. W. Page. An incision was made through the skin from a little below the elbow to just above the wrist down the middle of the forearm. The skin was reflected on either side and the tendons, which were no thicker than stout twine, were split for about one and a half inches and the halves were severed above and below on opposite sides. The fingers were then extended and the two halves of the divided tendons were allowed to slide on one another as much as was necessary and were then united with one or two sutures of No. 1 silk. In this way four tendons of the flexor sublimis digitorum, the flexor longus pollicis tendon, and, strange as it may sound, six strands of the flexor profundus tendons were divided, lengthened, and sutured. The latter tendons were so blended and adherent in the depths of the wrist that there seemed no end to the tiny strips which were separated from the mass and divided until all the terminal phalanges could be extended. Confusion was prevented among the number of tendon ends by employing guide sutures. The sublimis tendons as they were divided were transfixed by a guide suture and drawn on one side. The profundus and flexor longus pollicis tendons were then treated in the same manner. The deepest tendons were sutured first and afterwards the superficial ones. No tourniquet was employed and only one or two vessels required clamping and hardly any ligature, although the radial, ulna, and anterior interosseous vessels were exposed in the wound. The whole operation was strangely free from hæmorrhage and oozing. The muscles exposed were pale, firm, fibrous, and dry and very unlike the normal succulent vascular muscles of children. The operation lasted for two hours. The arm was put up with the fingers fully extended on a posterior splint carefully padded. The stitches were out in a week and the wound healed by first intention.

The after-treatment consisted of massage and passive movement every day from a fortnight after the operation. The child wore a back-splint at night as there were signs of further contraction occurring. During the day the sound arm was tied up inside her clothes and she was supplied with plenty of toys to encourage her to use her injured arm.

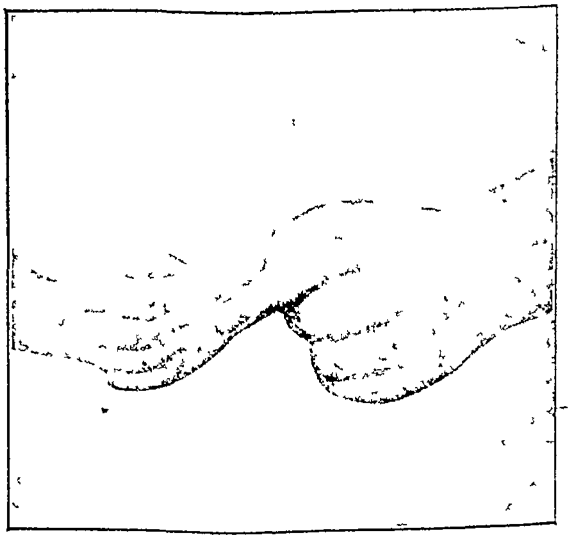
CASE 2.—A little boy, aged four years, was taken to the out-patient department at the Metropolitan Hospital on May 12th, 1900, suffering from contracture of the left forearm. On March 15th the upper part of his left forearm was crushed, producing extensive swelling from effusion of blood. Fracture was excluded by x rays. The arm was placed upon an external angular splint and lightly bandaged, as it was excessively painful. About five weeks later contraction of

FIG. 1.



Contraction of the flexor tendons. When the wrist is extended the fingers become flexed at the inter-phalangeal joints. The top joint of the thumb is also flexed.

FIG. 2



Contraction of the flexor tendons When the wrist is fully flexed the fingers become extended.

all the long flexor tendons commenced, and when he was seen by Mr. Barnard on May 12th, eight weeks after the accident, his left hand was in the typical position of *main en griffe*. The accompanying illustrations show the sign on which so much stress has been laid by Mr. Littlewood, that when the wrist is flexed the fingers extend and that when the wrist is extended the two inter-phalangeal joints of the fingers and the terminal joint of the thumb are fully flexed. The forearm was, moreover, fully pronated and fixed. There was no definite anæsthesia of the hand, although the skin of the digits was smooth and glossy and the whole hand much colder than its fellow The most patient and persistent massage, passive movements, and electrical treatment produced not only no improvement but the contracture steadily progressed.

On May 30th, about 11 weeks after the injury, Mr. Barnard operated by the method already described The tendons of the flexor sublimis profundus and flexor longus pollicis were split, divided, lengthened, and sutured in a manner identical with that described in the previous case The profundus tendons were not so adherent and matted as in Case 1, but the absence of hæmorrhage and the dryness of the wound were nearly as marked This was the first time that Mr. Barnard had performed this operation, and when after one and a half hours of tedious work on tiny tendons Mr. Barnard saw the mass of ragged ends and knotted silk in the wound the prognosis appeared to him to be so hopeless that he did not attempt to deal with the pronators of the arm

The wound healed by first intention, and in a very short time it was clear that the tendons had united past expectation. The common profundus tendon to the index and second finger did not act for some weeks, and this was explained by the fact that it was not sufficiently lengthened at the operation and had to be united end to end. The same tactics as have been described in Case 1 were adopted to prevent recontracture and to compel the child to use the lame hand. The progress of the case was satisfactory. A chronic painless whitlow appeared on the index finger of this case as in the other. Improvement was so marked after four months that the mother wished something to be done for the loss of rotation in the forearm

On Oct. 20th Mr. Barnard again operated. An incision was made partly through the upper end of the old scar but extending nearly to the elbow. The insertion of the pronator radii teres was found and the radial artery and nerve were separated from it The muscle was then split and divided on opposite sides, as the flexor tendons had been. An attempt was then made to supinate the forearm but this entirely failed An incision down to the bone through the periosteum was then made over the lower one and a half inches of the ulna between the flexor and extensor carpi ulnaris and with a periosteal elevator the attachment of the pronator quadratus was separated from the ulna The forearm was then readily supinated by the exercise of a little force The pronator radii teres was sutured in the upper wound and both incisions were closed The forearm was fixed fully supinated upon a splint

The after-treatment consisted of a splint at night and passive movement and massage every day. Pronation partially recurred as the masseuse when performing passive pronation and supination did not fix the ulna by flexing the elbow, and rotated the forearm from the hand and not from the end of the radius and ulna; however, rotation is fair, whereas previously to the second operation it was absent

Remarks by Mr. BARNARD —The present condition of both these cases is almost identical. The fingers and thumb are straight and the short muscles of the hand can act freely upon the digits, with the exception of the short muscles of the thumb in Case 1, which are still hard, contracted, and nearly powerless All the flexor tendons have apparently united so that partial flexion can be performed and the children can grasp a stick or pick up a pin, but neither child can make a fist The range of movement in the cicatricial muscles is only sufficient to half-flex the fingers Both cases, however, are still steadily improving, and I hope the result may be much better. In Mr. Page's case improvement was not well marked until 10 months after operation, and five and eight months only have elapsed since the operation on Case 1 and Case 2 respectively. Both cases were shown at the Medical Society of London on Feb. 11th, 1901, and a very favourable opinion was expressed as to the results of this method of operation I should like to record my indebtedness to Mr. J. K. S. Fleming and Mr F. Sanger, my house surgeons, not only for their assistance at these tedious operations, but for the care which they showed in the after treatment of the cases.

Contracture in muscles arises either from a primary lesion of the muscles when it is said to be myogenic or it is secondary to some lesion of the nervous system. The two cases of flexor contraction recorded here were myogenic in origin Case 1 was undoubtedly a case of Volkmann's ischæmic contraction Case 2 probably was the result of a severe contusion of the muscles and not of a long period of anæmia.

The circumstances under which a myogenic contracture may occur appear to be as follows. 1. When splints are applied too tightly to the forearm or elbow for fractures of the lower end of the humerus or the bones of the forearm. Frequently more or less of the skin sloughs, but this complication does not necessarily occur. 2 As the result of the application of Esmarch's elastic bandage or cord for too long a period to a limb, either during a bloodless operation or for auto-transfusion in collapsed cases. R Volkmann,[1] however, confesses that he has never seen an instance of the latter. It would appear that contracture may follow the application of an Esmarch's cord for little more than one hour. 3 When the main artery of the limb has been ligated, ruptured, or contused 4 Long continued and severe cold may produce a similar result, as has been shown by the experiments of Kraske[2] The contractures which result under the above circumstances may all be considered ischæmic in origin The last cause which will be considered is hardly ischæmic in nature, although the resulting contracture is strictly myogenic 5 After rupture or severe contusions of the flexor muscles in very young children. Thus König records a case in which the flexors of the forearm were ruptured in delivering a child and contracture followed. These cases are similar to contracture of the sterno mastoid muscle after its rupture during delivery in breech presentation. The second case reported here would appear to belong to this class

We must clearly distinguish these cases of contracture which are myogenic in origin from those which are primarily nervous Thus when one group of muscles are paralysed in the leg in acute anterior poliomyelitis contraction occurs in the healthy opponents and deformity results, or again, when ulnar paralysis occurs and the interossei muscles are powerless to resist certain actions of the long flexors of the forearm, these normal muscles contract and produce the typical claw hand. There is also the great group of spastic contractures which follow lesions in the brain or upper neuron (Little's disease) In this case all the muscles tend to pass into a contracted condition, but the stronger groups prevail. In these classes of deformity the cause is undoubtedly a primary nerve lesion In the group of cases described first by Volkmann and in that which is placed in the fifth division of causes above we must regard the contracture as a result of a direct injury to the muscle

The pathology of the cases arising from laceration or contusion of a muscle can easily be disposed of. The delicate vascular immature muscle of a young child is lacerated or pulped by a severe injury The delicate connective tissue between the bundles and fibres cannot prevent the extravasation of blood at the time or the reparative inflammatory process which follows from spreading widely throughout the muscle The immature muscle fibre is probably also more susceptible to injury and atrophies The muscle is more or less replaced by connective tissue and this undergoes cicatricial contraction Hence the contracture so common in congenital wry neck, in the case already referred to, reported by Konig, and in Case 2 recorded above Mr. Littlewood thinks that this explanation will cover all cases and that the tight bandage and splints are only scapegoats

The pathology of the cases due to the four first causes—viz, tight splints, tourniquets, injuries of arteries, and continuous cold—has led to much discussion. Volkmann and Kraske hold that the muscle-fibre more or less deprived of blood coagulates and passes into a condition of rigor mortis This change is indicated by the immediate paralysis and partial contracture of the hand. The dead muscle fibre is disintegrated and removed and a reparative hyperplasia of the perimysium follows As this develops into fibrous tissue the contracture appears—that is to say, from a month to six weeks after the injury. Volkmann[3] supports his view that the contracture is not nervous in origin, not only by the fact that Kraske actually produced and saw such changes occurring in animals under similar circumstances, but he proceeds to point out that paralysis and contracture appear together in these conditions in less than a month after injury, whereas in conditions where the contracture follows a nervous lesion it is delayed for months or even years. There is no doubt that such a direct destruction of muscle-fibres does occur, but there seems no reason why the delicate axis-cylinder of the nerves or even the end-plates may not be as sensitive to anæmia and pressure as the muscle-fibre itself. This was the view apparently taken by the late Mr. William Anderson.[4]

[2] Centralblatt für Chirurgie, 1879, No. 12.

These cases often show signs which appear to support a partial nervous origin. In several recorded cases there has been dulled sensation, if not anæsthesia of the hand. In both my cases the fingers became glossy and cold, and chronic painless whitlows developed some weeks after. It is, moreover, curious how few of these cases have complained of the splint being painful, even when they were applied to a fracture of the forearm. Dr. W. S. Hedley recently examined the muscles of the forearm in Case 2, and reported that he obtained the reaction of degeneration, although he admitted examination with the strong currents necessary was very difficult in one so young. If the muscle only had been injured one would have expected those fibres which remained intact to give a normal electrical reaction. Mr. Page also found the reaction of degeneration in his case. Perhaps the destruction of terminal nerve elements (axis-cylinder and end-plate) may prevent a regeneration of the muscle-fibre which might otherwise occur. It is, however, certain, as Volkmann points out, that these cases of ischæmic contracture differ widely from those where the muscle atrophies and much later contracts after a nervous lesion.

The history of the treatment of this very serious deformity shows a steady progress since Volkmann first described it. In the first communication on the subject he says: "We give these sad cases an almost absolutely bad prognosis. The flexor contraction of the fingers and of the wrist-joint obstinately resists all attempts to rectify it by stimulation with electricity, by passive movements, and by forcible extension under chloroform narcosis so that at last one will even be compelled to amputate." And in his later paper (1881) he remarks: "One will break the bones and tear the tendons before the muscles will give." Volkmann, however, gave a better prognosis for the similar condition in the leg, for here tenotomy was applicable and gave very fair results. The next attempt at treatment appears to have been to divide all the flexor tendons in the wrist and straighten the fingers. This was practised by Mr. Edmund Owen and Mr. Davies Colley, and no doubt by many others. The results appear to have been unsatisfactory. The fingers were straight, so that the short muscles of the hand could act upon them, but they were almost useless. In many cases contracture recurred after a time. At a meeting of the Harveian Society in March, 1898, Mr. Raymond Johnson[5] showed a boy, aged eight years, in whom he had resected a piece of the radius and ulna so as to render the tendons relatively longer. The hand was much improved, but the bones had unfortunately not united. Still, Mr. Owen,[6] speaking of his own experience of tenotomy, thought this the better treatment.

The method employed in the two cases reported above appears to have been independently devised by Mr. H. Littlewood[7] and Mr. H. W. Page.[8] The former performed the operation first; the latter was the first to publish it. No further description is necessary of the technique of their method except to say that Mr. Littlewood's method of using guide sutures is most useful, and the necessity for it is emphasised by the fact that Mr. Page was in some doubt if he had sutured the right tendon ends together. I do not think a tourniquet will be found necessary in any of these cases. The operation is more than an hour in duration and it does not seem advisable to submit the damaged limb to a further period of anæmia.[9]

In conclusion, it seems a matter for congratulation that a method has at last been devised by which these cases, which must always be a subject of regret to those responsible for them, can at least be palliated.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Sporothrix Schenckii.—Life-history of the Bacillus Coli Communis.—Tuberculosis of the Female Genital Organs.—Adeno sarcoma of the Kidney.—Cancerous and Calculous Disease of the Pancreas.

A MEETING of this society was held on April 16th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Mr. ALEXANDER FOULERTON made a communication on the Morphology and Pathogenic Action of Sporothrix Schenckii. The organism was a recent addition to the list of pathogenic mould fungi which had been isolated by Schenck and by Hektoen from two very similar cases in which a wound of the finger had been followed by a lymphangitis extending up to the forearm, and was followed by abscesses and ulceration. Orphuls and Moffit had recorded a fatal infection by what was probably the same parasite. In the last case numerous ovoid bodies had been found in the pus of various abscesses scattered over the body; culture tubes inoculated from this pus yielded a growth of a mould fungus. This fungus when injected into a rabbit produced nodules in the lungs and liver which contained the spore-like bodies, and from which a growth of the mould fungus was obtained. Mr. Foulerton showed cultures of the organism and sections of the lesions from infected animals, the specimens being prepared from a culture of the organism which Professor Hektoen had obtained from his case. In inoculated animals only the oval "spore form" was found in the lesions, and there seemed to be good reason for accepting Hektoen's suggestion that the "spore forms" were capable of reproduction as such. Mr. Foulerton thought that appearances seen in cultures on artificial media also suggested a reproduction of spores by direct budding from other spores. It was not quite certain whether the "spore forms" were really spores, or conidia, in the usual sense of the word; they seemed to more closely resemble the "yeast form" of, for instance, oidium albicans. These yeast forms of oidium could be cultivated as such on various media, but when transplanted to other media a development of mycelium occurred. Similarly in the secondary nodule produced by infecting rabbits with oidium albicans only the "yeast form" and no mycelium might be seen. The action of sporothrix Schenckii on lower animals was rather uncertain, but white mice appeared to be the most susceptible. In these animals an inoculation into the subcutaneous tissue was followed by an infection of the tissue in the neighbourhood of the site of inoculation, with sometimes an infection of internal organs as well. In guinea-pigs the susceptibility of individual animals varied considerably. In one case a large nodule in the lung followed an intra-peritoneal injection. In other cases the animal escaped infection. The tissue-changes found in the lesion were represented by collections of round cells having the general appearance of a granuloma. The cells might afterwards undergo caseation or break down into a greyish purulent fluid. The "spore forms" of the parasites were found in the lesions in great numbers, either lying free between the tissue cells or as small masses plugging the capillaries.

Mr W. O. C. PAKES read a paper on the Life-history of the Bacillus Coli Communis. No two bacteriologists were precisely agreed as to what organisms were typical of this bacillus, what were atypical, and what belonged to the para-colon group. He would confine his attention to what most observers regarded as the typical bacillus coli communis, but would describe some of the observations which he had made during the examination of a large number of strains of the bacillus coli communis. Out of a large number of bacilli isolated from water, fæces, &c., he had obtained 52 which were of such a nature that they might be described as quite typical. They were short, round-ended bacilli, were motile, did not form spores or stain by Gram's method; they produced indol in nutrient broth, did not liquefy gelatin, but formed typical colours on plates; they produced a yellowish or brownish growth on potato and coagulated milk generally after about 48 hours. In addition to this they fermented sodium formate, *d* glucose and lactose, reduced neutral red, but did not decompose urea into ammonium carbonate. When these 52 strains were grown upon media containing saccharose or glycerine, however, it was found that there was a distinct difference between them; some fermented both, some only one, and some neither, so that there might be said to be four varieties of typical bacilli from their reaction to these media. In the course of the paper Mr. Pakes said that he could not agree with Dr. W. Hunter when he stated that he looked upon the reduction of neutral red as a specific reaction in the diagnosis of the bacillus coli, for the same reaction was produced by the proteus vulgaris, bacillus prodigiosus, and bacillus Kiliense. He thought that Grimbert, Péré, and other observers were mistaken in making definite statements to the effect that the bacillus coli did not ferment glycerine or that adult-derived bacillus coli could not ferment saccharose, because none of his strain had been obtained from the fæces of children.

Dr. G. F. STILL read a paper on Tuberculosis of the Female Genital Organs in Childhood. A specimen of tuberculous caseation in the Fallopian tubes and uterus from a girl, aged four and a half years, was exhibited. The necropsy had shown some adhesions of the liver and spleen to the parietal peritoneum, but no general peritonitis; there were caseous tuberculous foci in the brain and lungs with tuberculous dactylitis and a glandular post-pharyngeal abscess. Reference was made to 12 other similar cases which had come under his (Dr. Still's) observation, and it was pointed out that this condition was not very rare in children. In his experience 9·5 per cent. of tuberculous female children under 12 years of age showed tuberculosis of the genital organs, whilst more than one-third (about 37 per cent.) of the cases of tuberculous peritonitis in female children showed tuberculous lesions in the Fallopian tubes or uterus. Of 13 cases of tuberculosis of the genital organs in children nine showed tuberculosis in the Fallopian tubes, in eight the uterus also was affected, and in only one was the ovary noted as tuberculous. The close association with tuberculous peritonitis was shown by the fact that 10 out of these 13 cases showed more or less generalised tuberculous peritonitis. This association might be interpreted equally well to mean that infection reached the peritoneum through the genital tract or *vice versâ*. The important practical point whether the female genital tract was to be regarded as one of the channels of infection for tuberculosis in childhood was difficult to determine; but if so, tuberculous peritonitis should be commoner in girls than in boys. Dr. Still's statistics showed that there was no marked difference in the incidence on the sexes, whilst other observers had found tuberculous peritonitis decidedly commoner in boys. The greater frequency of tuberculosis in the Fallopian tubes than in the uterus and the absence in all the cases of affection of the cervix and vagina also seemed opposed to this view. Moreover, there were reasons for supposing that the passage of micro-organisms from the vagina to the peritoneum was difficult, whereas in the opposite direction the passage was easy. The facts that when only part of the Fallopian tubes was affected it was the part nearer the peritoneal opening, and that the Fallopian tubes were sometimes affected without lesion of the uterus, whereas in no case was the uterus affected without lesion of the tubes, seemed to point to extension downwards from the peritoneum. On the whole the evidence seemed opposed to primary infection through the genital tract in children, although the possibility of such infection in rare cases could not be denied.—The PRESIDENT remarked that he was inclined to agree with Dr. Still as to the unlikelihood of infection being introduced from without through the genital organs. He did not think it occurred in either male or in female children.—Mr. J. H. TARGETT remarked that he had examined a great many cases of tuberculous salpingitis at all ages and he quite agreed with Dr. Still's conclusions. The extreme rarity of tuberculosis of the cervix was another fact supporting those views. He did not suppose that he (Mr. Targett) had met with 10 instances. Again, he had examined hundreds of curettings and not a dozen of them proved to be tuberculous. Tuberculosis of the tubes was quite common and, in his opinion, this was probably a primary seat of the disease, which sometimes spread thence to the uterus. In the earlier stages of tuberculous salpingitis there was a liability to hæmorrhage; in the later stages he had often found large quantities of cholesterin. Did this mean previous hæmorrhage? If so, these cases had been at one time hæmorrhagic salpingitis and thus tuberculosis might be a cause of hæmorrhagic salpingitis.—Dr. STILL, in reply, said that the cases recorded by him were not the earliest age at which the disease occurred. A case had been recorded by a French observer at the age of six weeks. He could not think that sexual intercourse was a means of infection. The probability was against it. In nine out of 23 adult cases of tuberculous peritonitis the genitals were affected as well.

Dr. MORLEY FLETCHER read a paper on a case of Adeno-Sarcoma of the Kidney. The tumour was removed post mortem from the body of a female child, aged three years, who had been under the care of Mr. Howard Marsh in St. Bartholomew's Hospital. Secondary nodules were found in the liver and lungs. Microscopically the growth resembled a round-celled sarcoma, but contained in addition epithelial structures resembling ducts The tumour did not contain muscle fibres. Sections and photographs of the growth were shown. Dr. Fletcher considered that the growth should be classed as an adeno-sarcoma and that it belonged to the group of congenital renal tumours first fully described by Birsch-Hirschfeld. Comparatively few cases had been fully reported in this country. Cases brought before the Pathological Society by Mr. F. F. Paul and Mr. Edgar Willett were in all probability of the same nature. The view most commonly held was that they were derived from the Wolffian body.

Dr. F. PARKES WEBER read notes of a case of Cancerous and Calculous Disease of the Pancreas in which Suppuration Supervened. The pancreas was replaced by a coarse, tough, fibrous meshwork, the spaces in which were of various sizes and were filled with gritty, calculous material, pus, and what appeared to be the remnants of pancreatic tissue. Microscopically the fibrous framework was found to consist of typical spheroidal-celled carcinoma. There was a fistulous communication leading from one of the suppurating cavities in the pancreas to the pyloric end of the stomach. The stomach was somewhat dilated, but there was no actual stricture of the pylorus. The patient was an extremely cachectic and anæmic man, aged 56 years, whose mother was said to have died from cancer of the stomach. One and a half years ago he began to suffer from abdominal pains. He sometimes vomited but had never had hæmatemesis. The hæmoglobin in his blood was estimated at only 20 per cent. of the normal. On some evenings slight pyrexia was noted. The urine was of low specific gravity and contained a little albumin but no sugar. The gastric contents one hour after a test-breakfast contained lactic acid but no hydrochloric acid. By abdominal palpation no tumour was felt. Death occurred from syncope about a week after admission to hospital. At the necropsy no malignant disease other than that already mentioned was found. No fat necrosis was noticed. The liver, weighing 48 ounces, showed great fatty change as well as a moderate degree of interacinous fibrosis and evidence of the association of recent inflammation with the older connective tissue increase. The cancer of the pancreas seemed to have been primary, and the interest of the case lay in the occurrence of cancer together with calculi of the pancreas, an association which resembled the well-known connexion between cholelithiasis and primary malignant disease of the gall-bladder and bile-ducts.

Dr. R. SALUSBURY TREVOR (introduced by Dr. H. D. Rolleston) exhibited a Small Cyst which be found on the under surface of a diaphragm taken from a patient who had died from cirrhotic ascites.

CLINICAL SOCIETY OF LONDON.

Volvulus of the Ileum with Severe Intestinal Hæmorrhage.—Ureteral Calculus simulating Vesical Calculus.—An Attempt at the Antenatal Treatment of Hæmophilia.—Poisoning by the External Use of Aniline Oil.

A MEETING of this society was held on April 12th, Dr. SIDNEY COUPLAND, Vice-President, being in the chair.

Dr. J. H. BRYANT read a paper on a case of Volvulus of the Ileum with Severe Intestinal Hæmorrhage. The patient, a man, aged 21 years, was admitted into Guy's Hospital on Sept. 18th, 1900, with symptoms resembling intestinal colic which had come on after eating a large quantity of damson tart for supper. His pulse was 80, his temperature was 99° F., and his respirations were 24. The abdomen was not distended, but the lower part was rigid. A hard mass was felt below and to the left of the umbilicus. During the next day the pain continued and in the evening, about 8 P.M., he became very collapsed and passed about a pint of bright red blood and a large mass of undigested damson skins of about the size of a tennis-ball. He was so blanched and collapsed that injections of strychnine and subcutaneous infusion of normal saline solution were ordered. During the night he continued at intervals to pass blood. On the following day he was still collapsed and became restless and delirious. He died on the 20th at 5.30 A.M. Just before death he brought up a large quantity of feculent liquid. Post mortem a volvulus of the ileum was found, 100 centimetres of the gut being involved, the lowest portion of which was 10·5 centimetres above the ileo cæcal valve. The wall of the gut was much thickened and felt œdematous. The direction of the torsion was from left to right. The mesentery appeared to be much lengthened. There was no invagination of any portion of the intestine and no evidence of embolism or of thrombosis of any of the mesenteric vessels. The question of the diagnosis was discussed. After the occurrence of the hæmorrhage and the collapse the patient was thought to be suffering from localised peritonitis and possibly thrombosis or embolism of the mesenteric vessels. During life volvulus was not suspected. Hæmorrhage with any form of intestinal obstruction other than intussusception was of exceptional rarity; he (Dr. Bryant) had only been able to find one recorded case of volvulus of the small intestine in which much blood was passed per anum.—Dr. J. P. Zum Busch remarked that he had met with similar hæmorrhage per anum in association with obstruction of the bowel from hernia and he related an instance in a man, aged 74 years, with a hernia which became irreducible and herniotomy was performed, relieving the constriction. The next day he passed a pint of almost pure blood per anum and on the sixth day after the operation he died suddenly from cardiac failure. Post mortem the constricted intestine appeared to have resumed its normal appearance and there was no ulceration. He also referred to the case of a man, aged 40 years, who was suffering from strangulation of the bowel by a band of adhesions in which blood was similarly passed per anum.—Mr. T. H. Morse (Norwich) urged that it was desirable to operate in these cases for diagnostic purposes, a practice which he had adopted under local anæsthesia from eucaine, ethyl chloride, &c. He thought that in this instance an exploratory operation would have been justifiable.—Mr. Charters Symonds remarked that such cases were very rare; he had not seen a case since 1882. That patient was a boy, aged 18 years, who was seized with violent abdominal pain, but when admitted the symptoms were not urgent. As he did not recover the abdomen was opened and coils of small intestine were found matted together and formed a volvulus, and the patient died soon after. He was not unfamiliar with hæmorrhage per anum after hernial constriction and of this he had met with several examples; in one the hæmorrhage was severe enough to determine collapse. This pointed to the unwisdom of giving enemata in these cases. He agreed that such cases might be dealt with under local anæsthesia.—Dr. A. E. T. Longhurst asked why the patient was not operated upon when admitted.—Dr. Sidney Coupland observed that the reason of hæmorrhage in intussusception was because the strangulation of the bowel was incomplete. In Dr. Bryant's case he presumed that the obstruction was complete and the symptoms might have suggested the possibility of intussusception having preceded the volvulus.—Dr. Norman Dalton said they ought to distinguish between strangulation of the vessels and strangulation of the bowel, and he referred to a case of kinking of the splenic flexure which ended in perforation, the kink being caused by adhesions.—Dr. Bryant, in reply, said that in his case the blood-vessels had been completely obstructed, but the bowel itself was only incompletely obstructed. He had not operated on admission because this did not seem called for. He insisted on the difficulties which the diagnosis presented in such cases and the rarity of volvulus attended by hæmorrhage.

Mr. Francis J. Steward read a paper on a case of Ureteral Calculus Simulating Vesical Calculus. The patient, a man, aged 24 years, had suffered for three years from attacks of painful micturition accompanied by hæmaturia. These attacks were slight at first but later became more severe. A week before admission into Guy's Hospital pain became much more severe and the urine became scarlet in colour and continued so until admission. On admission, on August 9th, 1900, there was a considerable amount of blood and a little pus in the urine. There was severe pain in the perineum and at the end of the penis both during and apart from micturition. There were no pain, no tenderness, and no fulness over either kidney or ureter. The bladder was sounded with a negative result and two radiographs were taken, but neither showed anything abnormal. The case was thought to be one of encysted vesical calculus. On August 24th the bladder having been inflated with air was opened above the pubes and a stone was felt impacted in the right ureter two inches from the vesical orifice. The stone could not be moved down the ureter, so the wound was closed. At a second operation on Sept. 2nd an incision was made in the lower part of the right linea semilunaris and the abdomen was opened. The stone was then pushed up the ureter to a point just above the common iliac artery. The ureter was then incised and the stone removed. The incision in the ureter was closed by a continuous silk suture of No. 0 Chinese twist passing only through the outer coats, and the peritoneum was sewn over it. The abdominal incision was closed with the exception of the lower part, through which a gauze drain was passed down to the site of the sutured ureter. No leakage took place and the patient left the hospital quite well and free from all symptoms. He was last seen on Jan. 8th, 1901, and was then quite well. The calculus weighed nine grains and was cylindrical in shape, measuring about half an inch by one-third of an inch. It consisted probably of uric acid with a small deposit of phosphates in some places, the surface being very irregular and covered with small knobs. The chief point of interest was in the peculiarity of the symptoms, all of which pointed to vesical calculus, there never having been at any time a single sign or symptom of an unilateral lesion. The suprapubic cystotomy was rendered extremely easy and satisfactory by the air distension, the peritoneum being lifted well up, and the bladder reached with very little disturbance of the cellular tissue. The absence of the usual flooding of the wound on incising the bladder was another great advantage.—Mr. T. H. Kellock suggested that the stone in that position might possibly have been felt per rectum, and, if so, this would have obviated the incision of the bladder. He did not concur in the view that inflation of the bladder with air was so superior to water, because when the bladder was incised the air escaped at once, whereas water was slower to escape. He congratulated Mr. Steward on the success of his suture of the ureter, but remarked that if there had been any leakage this might have proved dangerous, and he wondered why he had not put in the drain from the ureter to the loin.—Dr. J. G. Glover asked if there was any dilatation of the ureter above the seat of obstruction by the stone.—Mr. Charters Symonds congratulated Mr. Steward on the success of his case. In illustration of the difficulty which the diagnosis sometimes presented he mentioned a case in which the urine had an odour suggesting fæcal contamination. A skiagram was made and was stated to show a stone in the bladder, though examination by the sound failed to reveal it. At a subsequent operation a stone was found in the lower end of the left ureter and this was evidently the stone which in the skiagram appeared to be in the bladder. He questioned whether normal urine was of itself a danger in the peritoneum.—Mr. Steward, in reply, adhered to his preference for inflation of the bladder with air instead of water. He put a gauze drain in front because to make a posterior incision it would have been necessary to turn the patient over and clean the skin of the back and he was already exhausted by the operation. The ureter was very little distended—in fact, he had been unable to work the stone up into the loin as he had intended. He admitted that normal urine might not be harmful, but as there had been pus in this patient's urine for some time it might well be septic.

Dr. W. H. B. Brook (Lincoln) read a paper entitled an Attempt at the Antenatal Treatment of Hæmophilia. In June, 1900, he had been consulted by a woman, aged 34 years, who was expecting her confinement early in the following October, whose family history showed a marked tendency to hæmophilia. A brother of her mother died at the age of 11 years from hæmorrhage following the extraction of a tooth. One brother died at the age of 12 years from gangrene following hæmorrhage into the knee-joint. The eldest son of the patient, aged 10 years, was a typical "bleeder," having repeatedly suffered from hæmorrhage into the joints, from the alveoli and gums at the second dentition, and from hæmaturia. Her second son, born in 1894, had hæmorrhage from the cord at birth, showed marked bruising at the age of three months, and died, aged 12 months, from cerebral hæmorrhage. At the birth of each of these children there was considerable post-partum hæmorrhage and the patient was very weak for some time afterwards. Both these children were white when born. With the view of, if possible, obviating this tendency to hæmophilia the patient during the remainder of her pregnancy was placed upon chloride of calcium in doses of 10 grains three times a day in order to increase the coagulability of the blood. Iron and strychnine with arsenic were also given with the object of improving the tone of the vascular system both of the mother and fœtus. The patient was delivered of a male child on Oct. 3rd, 1900; there was no post-partum hæmorrhage and she made an excellent recovery. The child was of a healthy mottled appearance and had shown no tendency to hæmorrhage, not even at the time of vaccination. At the present time he was in excellent health. The patient might yet show signs of the diathesis, but his brothers had shown symptoms before this age.—Dr. SIDNEY COUPLAND thought that while the treatment might have a good effect in respect of the mother it was *going too far to suppose that it could do much for the fœtus*, especially as it had been commenced at such a late period. A large number of observations of the kind would be required to prove its efficacy in this direction.—Dr. C. R. BOX asked Dr. Brook whether any members of that family had suffered from measles, scarlet fever, or other infectious disease, and whether any hæmorrhagic complications had been observed.—Dr. BROOK, in reply, remarked that the tendency of modern views was in favour of the curable nature of hæmophilia, and this fact had encouraged him to try the treatment even at that late period of gestation. He was unable to reply to the last question.

Dr. STCLAIR THOMSON read a paper on a case of Poisoning from the External Use of Aniline Oil. Equal parts of aniline oil and rectified spirits having been recommended as a vehicle for cocaine in order to produce local anæsthesia in the ear[1] Dr Thomson prescribed a 10 per cent. solution of cocaine in this menstruum for a colleague suffering from furunculosis. A small pledget of cotton-wool moistened with this solution was used at bedtime and the patient slept well. Next morning, as the pain threatened to return, he again made use of the drops about 5 A.M. At 7.30 A.M., while still in bed, he quite accidentally noticed a peculiar blueness of his finger nails and his wife remarked that his face was also blue. The face and hands were found to be of a decided dark blue colour, and this was noticeable in the skin under the finger nails and on the lips and tongue. There was no fever or mental disturbance. The pupils were normal. The respiration was quiet and easy. The pulse was small and somewhat increased in frequency, and when Dr. David Lees had examined the heart the left ventricle was enlarged to two finger-breadths outside the left nipple line. The patient had not previously had any heart trouble and there was nothing discoverable in the heart or lungs to account for the cyanosis. It was therefore ascribed to the toxic effect of the aniline oil on the red corpuscles. The blue colour gradually disappeared in the course of the day. The area of cardiac dulness again became normal and no murmur was discoverable. Reference was made to a communication made to the Académie de Médecine in July last by M. Landouzy and M. Georges Brouardel describing the cases of ten children who were seized with prostration, pallor, and blueness soon after wearing yellow shoes which had recently been coated with a pigment found to contain 90 per cent. of aniline. When this dye was applied to the shaven surface of the skin of guinea-pigs and rabbits they died asphyxiated in from 24 to 30 hours. Some unpublished cases of Dr. Kelynack described similar symptoms, together with gastro-intestinal catarrh and anæmia in chronic cases, among those employed in aniline works. Evidently the skin readily absorbed aniline, and this might give rise to alarming symptoms which could not otherwise be explicable.—Dr. CHARLES W. CHAPMAN said that he was the patient whose case had been described and remarked that the most important point seemed to be the cardiac dilatation, which had called for prolonged rest. Unless this were remembered in future cases a patient by getting about too soon might inflict permanent damage on the dilated heart. He also remarked upon the smallness of the dose.—Dr. LEWIS G. GLOVER, alluding to Dr. Thomson's remark that the symptoms reminded him of poisoning by antipyrin, asked whether any cardiac dilatation had been noticed in this connexion. He referred to a case in which large doses of exalgin had been taken and he had noticed marked blueness but no cardiac dilatation.—Dr. STCLAIR THOMSON, in reply, said that in a case of antipyrin poisoning he had noted some cardiac dilatation, but as the patient was suffering from typhoid fever the dilatation might possibly have been caused by the fever.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 11th, Dr. E. Wearne Clarke, the President, being in the chair.—Dr. G. Wilkinson showed: 1. A patient, aged 42 years, from whom the Right Half of the Lower Jaw had been Removed. He had had a tumour of the jaw for two years. The specimen with microscopic slide was shown—a dental cyst in the lining of which a large epitheliomatous tumour had developed. 2. A patient from whom a large Round and Spindle-celled Sarcoma had been removed from the naso-pharynx and right nasal fossa after supra-alveolar excision of the right upper jaw. 3. A patient who had been operated upon successfully for Ruptured Gastric *Ulcer seven hours after onset of symptoms* of rupture. 4. A case of Transverse Fracture of the Patella with close (? bony) union and perfect mobility of the joint treated by elastic compression, massage, and passive movements.—Dr. D. Burgess showed the following cases: 1. Disseminated Sclerosis with general (not "intention") Tremors. 2. Paraplegia following immediately on an attack of Rheumatic Fever. 3. Glossitis Exfoliatricans Marginata of three years' duration in a child. 4. A case of Hydatid of the Lung.—Dr. Arthur J. Hall showed the following cases: 1. Lymphangiectodes in a young man. The affection had been noticed since childhood and it occupied a large area over the lower half of the right scapular region extending round to the axilla. It consisted of numerous small groups of vesicle-like structures of a brownish colour containing clear fluid and consisting of dilated lymphatics. Here and there were small clusters of mixed lymphatic and blood capillary tufts. 2. Bilateral Rodent Ulcer of six years' duration in a woman. The new growths occupied the skin just beyond the outer angle of the right eye and the inner half of the left lower eyelid. Ulceration was slight on the right side and absent on the left side. There was no glandular enlargement. Microscopically it was indistinguishable from rodent ulcer. 3. A case of Extensive Psoriasis. 4. An unusual form of Occupation Dermatitis in an elderly man who had worked all his life as "finisher" in the electro-plating trade. In this occupation he handled a mixture of finely-powdered lime with sufficient oil to form a soft adhesive powder. Fissures which appeared in the course of an attack of dermatitis, instead of healing became larger and formed gradually enlarging ulcers. *The explanation* was that the lime becoming lodged in the fissures and being moistened with lymph formed a slight caustic which caused the ulceration. Protection of the fissures and ulcers soon brought about healing.—Dr. Hall also showed the following microscopic specimens:—(1) Squamous Epithelioma of the Mamma; (2) Rachitic Rib; (3) Skin showing a Deposit of Coal-dust in the Dermis (miners' marks); (4) Extreme Fatty Degeneration of the Myocardium, from a girl, 15 years of age, who had marked congenital syphilis and who died with symptoms of heart failure; and (5) Syphilitic Interstitial Myocarditis in a young man who died in an epileptic fit and in whom the whole of the left ventricle was permeated by fibrous tissue.—Dr. Wilkinson read a paper on Aseptic Methods in General Practice. The importance of asepsis in general practice was insisted upon and several simple methods of sterilising and keeping sterile instruments, catheters, and surgical dressings were demonstrated.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held in the Medical Society's Reading Room, Owens College, on April 10th, Dr. A. T.

---

[1] Dr. A. A. Gray THE LANCET, April 21st, 1900, p. 1125.

Wilkinson being in the chair.—Dr. D. Orr and Dr. R. G. Rows gave a lantern demonstration illustrating the Normal Cells in the Posterior Root Ganglia of the Dog and of the Human Subject; they also exhibited the degeneration which occurred in these cells in general paralysis of the insane. The nerve cells of the ganglia were grouped under five types, according to the variations in the size and arrangement of their chromophile elements; attention was directed to the fact that each variety of cell degenerated in a characteristic manner. Special mention was made of the difficulty encountered in procuring an efficient fixative for the delicate cells of the spinal ganglia, and the value of a mixture of saturated solution of corrosive sublimate and picric acid in equal parts in preference to inefficient fixatives, such as alcohol and formalin, was demonstrated. Spaces and shrunken cells were then shown to be artefacts due entirely to imperfect fixation or post-mortem change in the tissues.—Professor J. Dixon Mann showed the Stomach of a Patient who died from Malignant Disease of the Pylorus, together with a number of the Pupa-cases of a Dipterous Insect, probably the House-fly, which were found in the stomach after death. Nothing was observed during life that indicated the presence of the larvæ; none were seen in the frequent and copious vomit. The extreme narrowing of the pylorus caused by the carcinomatous deposit was sufficient to prevent the pupa-cases being evacuated by the bowels.—Mr. J. E. Platt showed a specimen of Cirsoid Aneurysm of the Forehead removed by operation. The patient was a male, aged 25 years, and the tumour had been growing for four years before operation. No history of injury or other cause for its growth could be discovered. It was fed chiefly by branches of the superficial temporal artery, but also to some extent by the supra-orbital and frontal arteries. Three large veins from its deep surface entered the diploë. The superficial temporal artery had been ligatured near the zygoma and the aneurysm was afterwards removed by dissection. The operation had not been attended by any great amount of hæmorrhage and the patient had made a rapid and complete recovery. The tumour was composed of a close network of thin-walled blood-vessels.—Dr. W. E. Fothergill showed a drawing of Multiple Ulcers of the Inner Side of the Left Thigh in a patient who was suffering from Kraurosis Vulvæ. The onset and appearance of the ulcers were much more suggestive of one of the infective granulomata than of malignant disease, but microscopical sections of a clipping from the edge of one of the ulcers (shown) clearly demonstrated the epitheliomatous nature of the condition.—Dr. T. N. Kelynack exhibited a number of coloured drawings, photographs, and other preparations illustrating the more important lesions met with in the recent cases of Arsenical Poisoning from contaminated beer occurring in Manchester and the surrounding districts.

Manchester Medical Society.—A meeting of this society was held on April 3rd, Mr. A. H. Young, the President, being in the chair.—Dr. J. Stavely Dick mentioned a case of Pneumonia which ran a mild course. The defervescence occurred on the ninth day, respirations, pulse, and heart sounds being all normal on that date. Next day there was a sudden attack of palpitation of short duration, the pulse being so irregular and intermittent as to be uncountable; this was followed by three days of apparently most satisfactory convalescence, then a return of the irregular cardiac rhythm and unexpected death in two hours. Dr. Dick suggested pulmonary thrombosis as the most probable cause of death; and also the *a priori* probability that the coagulability of the blood varied in different types of pneumonia, and that this might be a factor worth consideration in connexion with unexpected deaths in convalescence.—Dr. Dick also read notes of a case in which the cannula was removed three and a half years after operation for Laryngeal Diphtheria with a good result for three months, when reintroduction of the cannula became necessary during a severe attack of influenzal laryngitis.—Dr. A. T. Wilkinson showed two cases that had been under his care in the Manchester Royal Infirmary, Dr. F. Craven Moore describing the pathological conditions found post mortem. In the first case the patient was a man, aged 35 years, with marked mitral stenosis, internal and external pericarditis, and old femoral and recent renal thrombosis. The interest lay in the efficient protection of the general circulation and system by the great hypertrophy of the left auricle and right ventricle compared with the marked lung induration, &c., which in effect led to the fatal issue, though actually the man died from syncope. The left auricle contained 10 ounces of clot and showed efficient muscle. The left ventricle was normal. The heart weighed 26 ounces. The second case was that of a woman of cachectic appearance, aged 43 years, with gastric disturbance dating back one year and intense obstructive jaundice of four and a half months' standing. She had recurrent vomiting and severe epigastric pain. The vomited matter contained free HCl. There was neither sugar nor albumin in the deeply jaundiced urine. The liver was somewhat enlarged and the gall-bladder was distinctly palpable. Otherwise no tumour could be discovered. The patient went from bad to worse and with falling temperature and delirium she died from asthenia and cholæmia. The necropsy showed a dilated stomach and the first part of the duodenum was catarrhal; there was a new growth of the ampulla of Vater; the mucous membrane over the papilla was healthy; the pancreatic duct was dilated and the tissue was sclerosed.—Dr F. Villy made some remarks on some cases of Intubation for Laryngeal Diphtheria.—Dr. J. Dreschfeld mentioned a case of Sarcoma of the Pleura and showed specimens.

Folkestone Medical Society.—A meeting of this society was held at the residence of Dr. T. Eastes on April 3rd.—Mr. A. W. Read read a paper on the Clinical Relationship of the Various Forms of Bright's Disease and some of their Symptoms in which the difficulty of connecting chronic renal disease with antecedent acute nephritis was set forth. Reference was specially made to the insidiousness of chronic renal cirrhosis, advice being often sought for symptoms which apparently had no connexion with the kidney. Mr. Read spoke about the difficulty of establishing the relationship of the small white contracted kidney with antecedent nephritis on the one hand, and with the red granular kidney on the other. The second part of the paper made reference to uræmia, the various forms of dyspnœa or so-called uræmic asthma, and the relationship of the skin to the kidneys. Mr. Read remarked that frequently patients suffering from uræmia would refer to a period in the past during which they were wont to perspire freely; when this excessive action of the skin ceased vague symptoms of malaise came on and a toxæmic condition arose. The paper closed with a passing reference to the use of pilocarpin, morphia, and calomel in cases of renal disease.—A discussion followed in which the following took part: Dr. W. J. Tyson, Dr. C. Latter, Dr. P. V. Dodd, Dr. A. E. Larking, Dr. P. G. Lewis, Dr. W. L. Chubb, Mr. W. F. Chambers, and Mr. A. Randall Davis.

Bristol Medico-Chirurgical Society.—The seventh meeting of the session of this society was recently held in the Medical Library of University College, Dr D. S. Davies being in the chair.—Mr. T. Carwardine showed a patient after operation for a large Ventral Hernia.—Dr. L. Firth spoke on the condition of the patient.—Dr. Walter C. Swayne read notes on a series of cases of Cœliotomy for Diseases of the Uterus and Ovaries.—Mr. J. Ewens, Dr. E. H. Stack, Mr. Paul Bush, and Dr. Firth discussed the paper.—Mr. Munro Smith read, for Mr. A. W. Prichard, notes of several operations undertaken for the Closure of an Artificial Anus.—Dr. Firth and Mr. Carwardine remarked on the case.—Dr. Stack read notes of a case simulating Plague.—Dr. Davies, Dr. J. E. Shaw, Professor Stanley Kent, Dr. T. Fisher, and Dr. James Fletcher remarked on the case.

Wigan Medical Society.—A meeting of this society was held on April 11th, when Mr. Hugh E. Jones read a paper (which was illustrated by diagrams) on Glaucoma, with Special Reference to its Differential Diagnosis in Routine General Practice.—An interesting discussion followed and the following members took part in it: Mr. W. Latham (the President), Dr. F. Rees, Mr. C. M. Brady, Dr. J. Blair, Mr. J. H. Fletcher, Mr. E. H. Monks, and Dr. J. M. Boyd.

Cardiff Infirmary.—At the meeting of the managing committee of the Cardiff Infirmary held on April 11th it was reported that the new operation theatre was nearing completion, and it was hoped that it would be formally opened on June 6th. It was decided to invite Mr. Edmund Owen of St. Mary's Hospital, to perform the opening ceremony.

Reviews and Notices of Books.

Lehrbuch der Physiologie des Menschen. Von G. VON BUNGE, Professor in Basel. Erster Band: Sinne, Nerven, Muskeln, Fortpflanzung. In Acht-und-zwanzig Vorträgen. Mit 67 Abbildungen im Text und 2 Tafeln. (*Text-book of Human Physiology.* By Professor G. VON BUNGE of Basle. Vol. I.: Senses, Nerves, Muscles, Reproduction. In 28 Lectures. With 67 Illustrations in the Text and 2 Plates.) 8vo. Leipsic: F. C. W. Vogel. 1901. Pp. 381. Price 10*s.*

THE text-book here presented to the student by Professor G. von Bunge of Basle has some peculiarities. It is written in the form of a series of essays or lectures delivered, we presume, to his class—an arrangement which has the advantage of permitting a freer style of expression than is common in physiological treatises; in fact, Brücke's Vorlesungen constitute the only example with which we are acquainted of a work written on the same lines. The order in which the several subjects are considered is unusual, for Professor von Bunge commences with the consideration of the senses, which naturally leads to that of the brain and to the discussion of the subjects of sleep, hypnotism, and hybernation. Then follow chapters on the Sympathetic System of Nerves; on the General Physiology of the Nerves and Muscles; Animal Electricity, Voice and Speech, Generation and Heredity,—all subjects that are usually relegated to the close of a treatise on physiology. The reasons advanced by the author for commencing with the senses are that all our ideas are derived from and through them and that they therefore constitute the basis on which physiology must rest, whilst from another point of view they form the crown and summit of all human knowledge.

Professor von Bunge has produced an eminently interesting and readable book and this is mainly due to the clever manner in which he adduces facts ascertained by experiment or drawn from pathology to illustrate and to support his views. A well-told case, as readers of the works of Watson and Trousseau, Graves and Charcot and Latham, will readily admit is often more convincing than a dozen pages of reasoning, however logical it may be. This anecdotal mode of writing renders Professor von Bunge's treatise quite refreshing to read. He has collected from various sources some interesting facts in regard to pain, a subject which, whilst it looms large in medical practice, is often passed over in silence in works on physiology. He remarks incidentally that the laity generally, and the antivivisectionists in particular, have imbibed the erroneous idea that the deeper the cut and the more deeply seated the organ the more acute is the pain experienced, whereas muscle and bones and tendons are nearly insensitive, and the same may be said of the brain and liver, though the growth of tumours or the process of degeneration may be accompanied by much suffering. The centres for pain are unknown, though they are probably to be located in the brain.

The chapter on Hearing is an excellent instance of the uncertainty of physiological inferences and statements that are usually accepted as perfectly demonstrated. In the first place, it seems to be established that fish are absolutely deaf, the stories of carp assembling at the sound of a bell being erroneously interpreted according to recent experiments, whilst removal of their semicircular canals has no influence on their equipoise or movements. The labyrinth seems in these animals to have nothing to do with hearing. Moreover, the utriculus and the semicircular canals can be removed in birds and even in mammals without producing deafness. The author points out that Ménière's disease may occur as a result of lesions and disturbances of the middle ear and of affections of the acoustic nerve and cerebellum, and Politzer has seen a case of complete absence of the semicircular canals in man without any disturbance of coördination. It is clear that the subject of hearing requires further research before the functions of the several parts can be allocated with certainty. The course of the sensory and motor fibres in the spinal cord and brain are well traced, the author relying for his illustrations upon Professor Edinger. It is remarkable to find that at the beginning of the twentieth century the functions of the cerebellum are almost entirely unknown, the last statement being that in many animals and in man it has little or nothing to do with the strength or activity of the muscles or with their coördination, whilst it is possibly, as Gall maintained, associated with the sexual instinct.

Some interesting observations are made upon sleep. The author has been at considerable pains to discover the origin of the statement frequently made that a Chinese mode of punishment is death by prevention of sleep. He traces it to the late Dr. Forbes Winslow who appears to have copied it from the *Louisville Semi monthly Medical News*, published in 1859, a journal that von Bunge has not been able to meet with. Still, if, as in Madame Manasseine's experiments, sleep be prevented for four or five days in young dogs they die, death being preceded by a great fall in the temperature and by a reduction in the number of the blood corpuscles from 5,000,000 to 2 000 000 per cubic millimetre and by considerable loss of weight. Man sleeps away one-third of his life and the dog two-thirds, but the sleep of the latter animal is very light; and Professor Bunge thinks that on this very circumstance depends the prehistoric association of man and the dog which he regards as a true symbiosis, the watchful and easily awakened dog guarding the more profoundly sleeping man from nocturnal beasts of prey, whilst man, with the aid of the dog, provides by hunting during the day the food for both. The observations on dreams are also good, and not less interesting is the chapter on Hypnotism. In conclusion, we have much pleasure in recommending Professor von Bunge's book to our readers.

A Text-book of the Diseases of Women. By H. T. GARRIGUES, A.M., M.D. Third edition, thoroughly revised. With 367 Illustrations London and Philadelphia: W. B. Saunders and Co. 1900 8vo. Pp 756. Price 18*s.*

THE fact that this book has reached a third edition is a proof that it has met the expectations of its author. His aim has been to write a practical text-book, and he may be said to have in part succeeded. In many instances the book enters into much more detail than is the case in the ordinary gynæcological text-book, while as regards modes of treatment Dr. Garrigues undoubtedly shows a considerable wealth of resource.

The work is divided into special and general diseases. The first part treats of the Development, Anatomy, and Physiology of the Pelvic Organs and Treatment in General. The second part includes an account of all the Various Diseases of the Genital Tract. The chapter upon the Development and the Anatomy of the Pelvic Organs is condensed from the author's article upon the subject in a "System of Gynæcology," by American authors. It gives a very complete account of the subject and is fully illustrated. The author's contention that the illustrations form a complete atlas of the embryology and anatomy of the female genitalia may be considered as correct. The illustrations throughout the whole book are numerous and on the whole are well chosen and well reproduced. The chapter upon General Etiology contains many useful suggestions. The subject of special examination and local treatment is [illegible] very fully discussed. It is interesting to note that Dr. Garrigues, although fully approving of the principles of the Weir-Mitchell treatment, is of opinion that gynæcological patients should have as much open-air exercise as possible, a point upon which we fully agree with him. The value of medical and electrical treatment is fully recognised, and, as is stated in the preface, they are whenever possible accorded precedence over surgical measures. In support of his recommendation of electrical treatment the report of the special committee appointed by the American Gynæcological Society is quoted, three out of its four members being in favour of electricity as a therapeutic measure. The portions of the book dealing with minor gynæcology and its disorders are much fuller and more complete than those devoted to the more serious diseases. This inequality of treatment destroys the book's claim to be a really first-class text-book. It is, however, eminently practical and will no doubt prove of value to such as are in need of just the information it furnishes. The printing is good and the index is sufficiently full.

A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M.A., M.D Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan; formerly Thompson Fellow in the University of Aberdeen and Assistant in the Pharmacological Institute of the University of Strassburg. London: Rebman, Limited. 1900. Pp. 730. 47 Engravings. Price 21*s.*

Text-books on pharmacology, materia medica, and therapeutics are numerous, and many of them are excellent manuals, and there would seem to be no call for an increase in their number. The volume now under consideration, however, is intended to supply a want in the teaching of the subject of pharmacology to those students who have completed the purely scientific branches of medicine and are beginning their clinical studies. Dr. Cushny has attempted to bridge over the hiatus which exists between the phenomena occurring in the normal organism and those which are elicited in the therapeutic use of drugs, to show how far the clinical effects of remedies may be explained by their action on the normal body, and how these in turn may be correlated with physiological phenomena. It necessarily follows that the subject is treated from the experimental standpoint and that the results of the laboratory investigator are made the basis of almost every statement. Starting with such ideas, which the author has consistently followed, a most interesting volume is the result.

The introduction, which occupies 42 pages, deals in a capable manner with the mode of action of drugs, their elective affinity, their chemical composition, their pharmacological action, their methods of administration, and their classification.

Part I. is headed "Organic Substances which are Characterised chiefly by their Local Action." These include the demulcents, emollients, flavouring substances, bitters, counter-irritants, and the like. Part II. is occupied with a consideration of "Organic Substances Characterised chiefly by their Action after Absorption." The author's remarks on alcohol are worthy of note. In answer to the question, "Is alcohol a food?" he remarks: "It would seem, therefore, that while alcohol undergoes combustion in the tissues and leads to the deposit of fat it is questionable how far it can replace the carbohydrates and fats in their relation to nitrogenous metabolism; that is, alcohol tends to prevent the waste of the fats and carbohydrates of the body, but probably is of little value in economising the nitrogenous waste. If alcohol is to be used as a food it must be associated with a diet rich in proteids and on this condition it can replace to some extent the ordinary foodstuffs."

The whole work has been conducted on sound scientific principles, the experiments have been carried out with care and skill, and the accounts given of them are full and easily comprehended and form a most valuable addition to our knowledge of the actions of drugs. A good example is that of the experiments performed to show the action of ether and chloroform. The effects on the central nervous system, the respiratory centre, the circulation, the blood, and metabolism of the tissues are carefully demonstrated; and the observations on the "cause of death" from these anæsthetics are interesting and instructive.

A typical example of the general plan on which the different drugs are discussed is yielded by the section on the Opium Series The opening remarks deal with the chemical characteristics of opium and its derivatives, then follows a description of the symptoms produced by their administration in animals and in man. The physiological action is next considered, the effect produced on the various systems of the body being clearly recounted. A list is given of the preparations of the drug as found in the pharmacopœias of the United States and Britain. The therapeutic uses of opium and its derivatives receive due attention and the symptoms of poisoning, both acute and chronic, are accurately described. It will thus be seen that the manual is made as complete as possible. We have not space to comment on the many other excellent accounts of the various drugs, but we would especially mention as well worthy of perusal the remarks on antipyretics (acetanilid and antipyrin series) and on the digitalis series.

Part III. is concerned with Combinations of the Alkalies, Alkaline Earths, Acids, and Allied Bodies; Part IV. describes the actions and therapeutic uses of "the Heavy Metals"; Part V. imparts useful information on Ferments, Secretions, and Toxalbumins; and Part VI., which only occupies a couple of pages, is headed Menstrua and Mechanical Remedies.

Taking the book as a whole, we consider it a most valuable publication and can thoroughly recommend it to our readers who desire reliable and exhaustive information on pharmacology.

Atlas and Epitome of Special Pathologic Histology. By Docent Dr. Hermann Durck, Assistant in the Pathologic Institute; Prosector to the Municipal Hospital L.I. in Munich. Authorised translation from the German. Edited by Ludvig Hektoen, M.D., Professor of Pathology in Rush Medical College, Chicago. Circulatory Organs; Respiratory Organs; Gastro-Intestinal Tract. With 130 Coloured Illustrations on 62 Lithographic Plates. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 158. Price 13*s.* net.

The present volume forms the first of a series of three designed to cover the whole ground usually embraced under the term "pathologic histology." These volumes enter also into the general series of hand atlases produced by the same publishers. In an address given at the Medical Graduates' College and Polyclinic Professor Osler said that instead of looking to the East, as in times past, for wisdom we should in the near future turn rather to the West, and at the present moment the west is certainly doing much to transmit the wisdom of Europe to English-speaking races, judging by the very large number of American translations of German works which are being published. It must be confessed that the importance of the works selected for translation and the general excellence of the publications justify this movement, and the present work forms no exception to the rule. The book appears to be not so much an atlas with descriptions of the plates as a concise systematic pathology which is excellently illustrated by the drawings reproduced. The plates are lithographs in colour and seem to be admirable representations of typical histological sections. It is interesting to compare them with some recent photographic illustrations of pathological processes which have appeared, and it must be confessed that the comparison is in favour of the lithographs. Photographs of sections, except for special purposes, are not very useful for demonstration, and it seems a pity to give up the advantage of colour which can accurately reproduce the effect of the stains which are of such great importance for the differentiation of the tissues. While recognising the value of such a book as the present there seems to be some danger of its improper use—the student is apt to consider these illustrations as substitutes for his own sections instead of merely aids by which he may learn to recognise what his own specimens teach. The author himself recognises this danger and deprecates the separation of the book from the teaching of the laboratory. The methods used in the preparation of the sections appear to be up-to-date, but there is attached to the descriptions of the figures no statement of the staining methods or the stains used; the magnification is in all cases given.

The lithographs are produced in Munich and are good. Unfortunately, this book, like so many containing plates, is indifferently dealt with by the binder and, unless we are unlucky in our copy, a moderate amount of wear and tear will leave very few plates undetached. The book, with the caution as to its use mentioned above, will prove a useful addition to the libraries of medical students and will probably be decidedly popular.

Terapia dell' Afasia e degli altri Disturbi del Linguaggio. Por H. CHARLTON BASTIAN, M.A., M.D. Londra, F R.S. Traduzione Italiana del Professore UMBERTO GABBI. Torino: Unione Tipografico-Editrice. 1901 Pagg. 470. Prezzo 6 lire. (*On Aphasia and other Defects of Speech.* By H. CHARLTON BASTIAN, M A., M.D. Lond, F R.S. Translated into Italian by Professor UMBERTO GABBI.)

THIS work is a translation of Dr. Charlton Bastian's book, "Aphasia and other Speech Defects," which in its English dress was reviewed in THE LANCET of Oct. 15th, 1898, p. 997. The book itself is an expansion of the Lumleian Lectures which Dr. Bastian delivered before the Royal College of Physicians of London in 1897 and which were published in full in our columns.[1] Dr. Bastian's views on this somewhat intricate subject are well known and if not universally accepted are in this work supported by plenty of confirmatory evidence. Shortly, he considers that the so-called motor areas in the brain are really sensory centres of "kinæsthetic type," and in connexion with speech processes he believes that there are two centres of this type—a glosso-kinæsthetic centre related to articulatory processes and a cheiro-kinæsthetic centre in connexion with writing processes. Besides these there are an auditory word centre and a visual word-centre—sensory centres—and lesions accounting for speech defects are to be looked for in those centres or in the fibres connecting them with each other or with the motor centres in the bulb, or in these motor centres themselves.

The problems involved in the consideration of such a subject as aphasia are by no means easy, neither can the matter be expressed in very simple language But Professor Gabbi has, we think, been very successful in his difficult task of translation from a foreign language and his work will be of the greatest value to those of our foreign medical brethren who cannot read an English treatise. Praise is due to the printing of the book which is very clear.

Affections Chirurgicales du Tronc, Mamelles, Organes Génitaux de la Femme: Statistique et Observations. (Surgical Affections of the Trunk, Breasts Female Genital Organs: Statistics and Observations) By Professor POLAILLON. With Illustrations. Paris: Octave Doin. 1901. Pp. 750.

THESE statistics are based upon the practice of Professor Polaillon during the 20 years from Jan. 1st, 1879, to Jan. 1st, 1899. When the practice of antiseptic and aseptic surgery had demonstrated how benign surgical operations had in general become most of the affections peculiar to the female genital organs appeared to be susceptible of cure by operative measures. The result was that operative gynæcology was practised to such an extent that in view of the immediately successful results the ultimate fate of the patient was in danger of being overlooked. As Professor Polaillon points out, the rôle of statistics is to recall us to the realities and to prove that operative success is not always synonymous with therapeutic success, and that the safety of operations is but relative. As he shows, in spite of the progress due to antisepsis and asepsis the mortality of major abdominal operations is still considerable. Even if it ever be reduced to *nil* for minor operations it must in complicated cases bear a relative proportion to the severity and length of the operation and the condition of the patient. It is chimerical to hope that the present operative mortality will ever entirely disappear, although in the future it may still be lessened to a considerable degree. The present collection of cases and statistics is one of much value, although owing to the fact that the figures for the whole 20 years are grouped together it is not so valuable as it would have been if they had been divided into four-yearly periods. In this way very interesting comparisons could have been drawn between the various periods. The book contains, however, some most interesting cases fully detailed and very complete statistical tables. It is impossible for us to summarise the figures here, but for anyone in search of results the work is one of importance. The book is a continuation of works of the same kind dealing with other parts of the body which have been already published by the author.

LIBRARY TABLE.

Diphtheria: Modern Views as to its Origin, Dissemination, Treatment, and Prevention. By JOHN C. THRESH, M.D Vict., and A. E. PORTER, M D Cantab. Chelmsford: John Dutton. 1901.—This is a little pamphlet of 16 pages which was compiled for the information of members of sanitary authorities at the request of the Sanitary Committee of the Essex County Council. It gives in plain and simple language information on the following points: (1) the cause of diphtheria; (2) the value of bacteriology in detection and diagnosis; (3) the value of antitoxin as a curative agent; and (4) the use of antitoxin in the prevention of the disease. The pamphlet should be exceedingly useful in explaining reasons for isolation and certain forms of treatment to those who naturally enough do not understand such matters at first. Any sensible man who has doubts as to the infectiveness of diphtheria, as to the need for isolation, or as to the value of the antitoxin treatment will have his doubts set at rest by reading the pamphlet. There are, of course, those who, like the rich man's brethren, would not be converted though one rose from the dead, and to such the facts stated will not naturally appeal, but to the ordinary mind they will carry conviction.

Sexual Debility in Man. By F. R. STURGIS, M.D. London: Rebman, Limited. 1901. Pp. 432. Price 12*s.* 6*d.*—"To the sexual cripples of the United States whose infirmities have in part contributed to his support, this book is gratefully dedicated by their obliged friend, the author." This is the dedication of Dr. Sturgis's book and one which, we think, is unfortunate For those to whom a book is dedicated are generally supposed to read it, and yet Dr. Sturgis says in his preface that the principal reason for writing it "is to introduce to the reading medical public sundry opinions." We really can see no reason why the book should have been written at all. The author's views upon the points mentioned in the preface are certainly sound, but there is nothing new in them. No medical man nowadays believes that masturbation, albeit a degraded and unclean habit, leads to such appalling mental and physical degeneration as is set out in quack pamphlets, neither does any believe that spermatorrhœa and the ordinary physiological seminal emission to which any healthy man leading a continent life is liable are the same thing. Why, then, write a book to make clear these points? Possibly, however, Dr. Sturgis wishes his friends, the sexual cripples, to read his book: if this is so he should not have filled the work with what we must call dirty stories. To our minds the publication of the book involves Dr. Sturgis in this dilemma: if it is meant for the medical profession there is nothing in it new or which, we should imagine, every medical man does not know; if he intends it for the sexual cripple there is a great deal too much matter and that of the wrong kind. If Dr. Sturgis reprinted very briefly his views on masturbation and nocturnal pollutions and published these views separately he might be the means of saving the ignorant and foolish from the den of the sexual quack. But as a contribution to medical literature the book is worth nothing.

---

[1] THE LANCET April 3rd (p 933), 10th (p 1005), and 24th (p. 1131), and May 1st (p. 1187), 1897

Rodney Stone. By A. CONAN DOYLE. London: Smith, Elder, and Co. 1901. Pp. 366. Price 6*s.*—This is a new edition of Dr. Conan Doyle's delightful story which was first published in 1896. So many people have read the book that we need not say much about it here, except that if anyone wants a well-written story full of incident and dealing with an interesting period he cannot do better than select "Rodney Stone." We wonder if it has ever occurred to the author to turn his book into a Drury Lane drama. The incidents of the prize-fight, the race from Brighton to London, and the closing scene where the wicked nobleman is fetched away by Old Nick in the shape of bailiffs would appeal to a popular audience.

The Column: A Novel. By CHARLES MARRIOTT. London: John Lane. 1901. Pp. 468. Price 6*s.*—This is a very cleverly written and, at the same time, a most aggravating book. It is scrappy and indeterminate, neither is there any definite plot; but it is full of cleverly drawn characters, none of whom, however, has much to do with any other. The most interesting one from our particular point of view is Dr. Caspar Gillies. He is a very original person and, we should say, would be hopelessly unsuccessful as a practitioner, but he must have been a genius, for he managed to make a little village orchestra play the B minor symphony of Schubert. Daphne, the chief female character, is a curious survival, a modern pagan, addicted to bathing with nothing on and to sitting in a dreamy unconscious state by an old Doric column which had been brought from Greece by her father, a famous Hellenist with a quaint family history. She first came into contact with the offensive prig whom she married—an exceedingly clever portrait, by the way—when playing the viola near this column at night while he lay beneath it with a broken leg. It is clever of Mr. Marriott to have given Daphne a viola to play, for that curious instrument, with its thin, sad tone, with its disproportion between its body and its scale, is an apt likeness of Daphne, who never seems to have been happy except when out of the body in one of her quasi-cataleptic intervals. We note, too, that just before she committed herself to the sea she deliberately bade the instrument farewell after having cut its strings—an act which, if it implies anything, implies an association in Daphne's mind between her personality and her viola. Mr. Marriott is evidently a young man as well as a young writer. Let him try to forget Meredith, Henry James, and Nathaniel Hawthorne; let him write another book with a plot and in a style of his own, and we dare to say that with his power of character-drawing it will be a really good work.

Analytical Records

FROM

THE LANCET LABORATORY.

NUTRABIN.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, LONDON, N.)

NUTRABIN is a rich proteid food made, as it is stated, with the proteids of milk and beef. Moreover, it contains the peptonic and pancreatic enzymes which are calculated to convert the proteids into assimilable proteoses. The preparation contains a relatively small proportion of carbohydrates and very little fat. Our analysis was as follows: moisture, 9·90 per cent.; mineral matter, 4·16 per cent.; proteids, 60·00 per cent., equal to nitrogen, 9·59 per cent.; fat, 1·20 per cent.; and carbohydrates, 24·74 per cent. The ash contains over 50 per cent. of soluble salts, chief amongst which is the dietetically important salt, phosphate of potassium. The proteids are for the most part in a soluble form, cold water extracting no less than 32·40 per cent. of the preparation. Doubtless a greater proportion than this is soluble in warm water. The greater part of the proteid matter is evidently derived from milk, for the cold water extract behaves like a solution of casein. Nutrabin is a cocoa-coloured powder possessing a strong vanilla flavour and odour. For use it is prepared much in the same way as cocoa. The flavour would not be regarded as agreeable by everyone, resembling that of a weak cocoa infusion associated with vanilla. It is undoubtedly a good nutrient, especially available for those cases in which the powers of nutrition and assimilation are weak.

NORFOLK CIDER (STILL).

(W. GAYMER AND SON, ATTLEBOROUGH.)

We have received two specimens of still cider in bottle, one described as very dry and the second as first quality dry. The results of analysis of the first were as follows: alcohol, by weight 5·25 per cent., by volume 6·55 per cent., equal to proof spirit 11·49 per cent.; extractives, 4·71 per cent.; ash mineral matter, 0·27 per cent.; volatile acidity reckoned as acetic acidity, 0·14 per cent.; fixed acidity reckoned as malic acid, 0·42 per cent.; and sugar, 0·25 per cent. The results of analysis of the second sample were as follows: alcohol, by weight 5·25 per cent., by volume 6·55 per cent., equal to proof spirit 11·49 per cent.; extractives, 5·88 per cent. mineral matter, 0·29 per cent.; volatile acidity equal to acetic acid, 0·19 per cent.; fixed acidity equal to malic acid, 0·38 per cent.; and sugar, 2·90 per cent. Both were excellent specimens of cider in perfectly sound condition and with delicate apple-like odour and acid flavour. The "dry" specimen might easily pass for a light Sauterne wine. Cider is a well-known wholesome beverage when sound and free from excessive acidity, as is the case with the specimens before us, and there are many who would prefer the still variety to the sparkling. An excess of carbonic acid gas is not always desirable. These specimens are similar to the sound cider drawn from the barrel. We could trace no objectionable preservatives. It is interesting to add that cider contains volatile ethers of the same character as those present in wine. We found in the "very dry" specimen before us that the volatile ethers amounted to 1·4 parts per 10,000. Lastly, the mineral matter of cider is rich in potash salt which when ignited produces potassium carbonate. This fact may account for the reputed value of cider as a beverage in gouty and rheumatic conditions.

PORCHERINE.

(PORCHERINE, LIMITED, 11, QUEEN VICTORIA-STREET, LONDON, E.C.)

"Porcherine" is described as a new sweetening product and the discovery of a French chemist, M. Porchere. A specimen which we received was a somewhat syrupy liquid with a most intense and persistent sweet taste. It is evidently the sodium salt of a coal-tar derivative. Both the ammonium group and the sulphonic group are present in the substance. On evaporating the liquid and igniting it an ash of sodium sulphate was left behind and the fumes possessed an aniline-like odour. On heating with soda lime "Porcherine" gives off ammonia freely. On adding dilute acid to the fluid a dense white substance separates which is probably the prime material. This dissolved in soda gives the fluid "Porcherine." From a number of investigations made in France "Porcherine" would appear to be without injury to health. The fluid is said to possess a sweetening power 250 times greater than sugar. It is suggested as a convenient sweetening agent for the use of the gouty and diabetic and for the purpose of sweetening confectionery, jams, mineral waters, &c. Its sweetening power is certainly remarkable.

EGYPTIAN FOOD.

(W. SYMINGTON AND CO., BOWDEN STEAM MILLS, MARKET HARBOROUGH.)

As is well known, the lentil is remarkably rich in proteids, more so than the pea or the bean, and further it is decidedly more digestible. The preparation before us is made from the best Egyptian lentils which are superior dietetically to any others. The food is well prepared and consists of a perfectly uniform flour. It possesses the characteristic flavour of the freshly-ground lentil, a flavour which, like that of coffee, may easily be sacrificed during the process of manufacture or preparation. The nourishing qualities of this food are unquestionable and we are glad to note that the manufacturers describe exactly what the food is upon the label of the tin, and this description according to the results of our examination is accurate.

NONPHOSS WAX VESTAS.

(THE NON POISONOUS STRIKE ANYWHERE MATCH SYNDICATE, LIMITED, 37, WALBROOK, LONDON, E.C.)

We have carefully examined these matches and we find that they are entirely free not only from the ordinary yellow phosphorus but from any kind of phosphorus. Amongst the ingredients which the heads contain are chlorate of potash and sulphur, the energetic chemical action of which is tempered by the presence of another body. It is satisfactory that makers have been stimulated under the pressure of public opinion to prepare a match which will not be injurious to the operatives employed in its manufacture. Further, the matches on ignition do not give rise to injurious phosphorous fumes. We cannot concede that the "nonphoss" match is as satisfactory from the point of view of striking as is the phosphorous match. Although it is true that it strikes anywhere it is not easily ignited and when ignition does occur it is accompanied with some splutter. The match certainly strikes best on the sand-paper rubber. However, we would most heartily encourage the production of such a match as great mischief has been done by the methods of manufacture hitherto adopted which involved the use of phosphorus.

(1) EXTRA STOUT; AND (2) INDIA PALE ALE.

(WHITBREAD AND CO., BRITANNIA-STREET, KING'S CROSS, LONDON, W.C.)

These bottled beers present the undoubted advantage of sparkling with the gas developed in the fermentation of the beer itself and not with added gas. We pointed out in THE LANCET of March 23rd, p. 882, that the sparkling quality of many beers upon the market depended not upon the gas generated in the beer itself by normal fermentation, but upon artificial gas forced into the liquid in the same way as soda water is made. We believe that such carbonated beer is not so wholesome or dietetically so satisfactory as is beer charged with its own natural gas. We have had the opportunity of witnessing the bottling beer process as carried out at Messrs. Whitbread's bottling factory. The beer is bottled at just that time when it will develop sufficient gas, and no more, to make the beverage agreeably sparkling. The result is a beer which is free from the sharp, harsh taste of carbonic acid artificially forced in. In the latter case the beer soon gets flat, while in the former the beer keeps its sparkling qualities for some time, a point which we believe is in favour of the digestible qualities of the beer. The analyses of the two specimens were as follows: extra stout—malt extractives, 7 31 per cent.; mineral matter, 0 35 per cent.; alcohol, by weight 5·44 per cent., by volume 6 78 cent., equal to proof spirit 11·89 per cent.; and proteids, 0·61 per cent. India pale ale—extractives, 3 01 per cent.; mineral matter, 0·21 per cent.; and alcohol, by weight 4 94 per cent., by volume 6 17 per cent., equal to proof spirit 10 81 per cent. The excellent proportion of malt extractives in the stout makes it undoubtedly a nutritious beverage and it is also easy of digestion. Both beers were in fine condition and were free from undue acidity and any objectionable constituents.

ABBEY'S EFFERVESCENT SALT.

(THE ABBEY EFFERVESCENT SALT CO., 144, QUEEN VICTORIA-STREET, LONDON, E.C.)

We have carefully examined this effervescent saline preparation and we find that it is quite free from objectionable ingredients. A feature of the salt is its remarkably uniform granulation, which while tending to preserve its effervescent qualities secures a steady effervescence when it is dissolved in water. The powder thus treated does not bubble or froth inconveniently and so the effervescing solution is comfortable to take. The powder is agreeable in character and of approved composition, and is evidently prepared from pure and refined salts. It is quite free from the contaminations sometimes found in effervescent powders of a similar nature and composition.

New Inventions.

PAGENSTECHER'S CELLULOID THREAD.

THE introduction of this thread is a decided advance in operative surgery, especially in abdominal surgery. The fine thread is the ideal suture for peritoneum as in the operation of gastro-enterostomy; it does not slip, is easily threaded, and it is easy and supple to stitch with. The tensile strength of the thread in proportion to its calibre is astounding, the strength is if anything increased by the process of sterilisation. There is only a slightly appreciable swelling of the thread after boiling it; any water absorbed by it can be withdrawn by preserving the thread in alcohol. Some months of experience with the thread have not given rise to any anxiety or complication. There is every reason to believe that although the thread is not absorbed yet it soon gets organised over and buried with an aseptic burial by the neighbouring tissues. The thicker thread is useful for ligating a large blood-vessel or a pedicle, for instance in the operations of hysterectomy, ovariotomy, and radical cure of hernia. The thread may be boiled many times without undergoing any deterioration and should entirely supersede silk as it is cheaper, more reliable, stronger, and more easily worked with The following method of sterilisation is recommended. From the hank obtained cut suitable lengths of thread and wind them on a glass reel. Boil for 20 minutes. Take the reel out with sterilised forceps and drop it into a wide-mouthed bottle containing 5 per cent. of phenol in methylated spirit There the thread can be preserved indefinitely. The thread may be obtained from Messrs. Reynolds and Branson, Limited, Leeds.

Leeds.

*** It seems to us that the fibre is not celluloid although apparently it contains celluloid, but though smelling strongly of camphor it is not very inflammable.— ED. L.

THE LANCET.

LONDON: SATURDAY, APRIL 20, 1901.

The Port of London.

The doings of the Port of London are always of interest both by virtue of their magnitude and of the importance which attaches to the proper carrying out of the precautionary measures against the introduction of disease. At the present time, when a large number of invalids convalescent from enteric fever are returning from the Cape, and when bubonic plague appears to be spreading in South Africa, it is a matter of great public concern that all practicable measures should be taken to reduce the chances of infection through transports. The importance of this matter is referred to by Dr. W. Collingridge, the medical officer of health of the Port of London, in his last half-yearly report. It appears that the authorities at the War Office were anxious that invalids returning from the Cape should be allowed to pass up the river and to proceed to Woolwich and the Local Government Board were asked to give their sanction to this. As an outcome of this request a conference was held at the Local Government Board Office between representatives of that department, of the Admiralty, of the War Office, and of the Port of London, and as a result it was arranged that in future all transport vessels are to call at Southampton, by which means the infectious sick can be removed to Netley Hospital. The vessel conveying the sick will then be disinfected by the Southampton Port Sanitary Authority who will furnish a certificate to this effect before she proceeds to her destination. These arrangements apparently apply to diseases other than plague, cholera, or yellow fever, cases of which will be dealt with in the usual manner under the Orders of the Local Government Board. It is satisfactory to hear that an amicable arrangement has been arrived at and that the port sanitary authorities will continue to deal with transports as with other vessels. As far as we are aware neither the Admiralty nor the War Office have at their disposal adequate means for dealing with an infected vessel in the manner in which such a vessel is dealt with by our port sanitary authorities, and it is clearly in the interest of the public health that administration with regard to ship-borne disease shall be focussed in the public health department of the country. Were the Admiralty or the War Office to practise quarantine foreign nations might find some difficulty in reconciling the teachings of our country with our practice.

With regard to plague the proceedings taken in the Port of London in the direction of the control or destruction of rats is a matter of consequence, and Dr. Collingridge embraces in his report an interesting and judicial *résumé* of our present knowledge as to the relation of plague in rats to plague in the human species. He also furnishes reports contributed by the several London dock companies setting out what are the actual precautions taken in respect of rats. Vigorous as some of these measures are they do not, as Dr. Collingridge observes, altogether suffice to ensure safety, and he gives an interesting account of experiments made by Dr. Danysz of the Pasteur Institute in the direction of exterminating rats by means of an organism which for rats is pathogenic but for man harmless, the organism in question having been isolated by Dr. Danysz from field-mice suffering from an infectious malady. The steps by which this experimenter accentuated the virulence of the microbe are full of interest and the results of his work are decidedly promising. Perhaps the most remarkable results were those obtained by placing 200 rats in a limited section of one of the Paris sewers. Cultures of the bacillus were distributed in the sewer, and eight days afterwards an epidemic broke out amongst the rats which proved fatal to 80 of them. Half of these were examined and lesions typical of those produced by the bacillus were detected. The remaining 40 which were left in the sewer were eaten by the survivors. At a later date only eight live rats were found, but, unfortunately, these escaped. Apparently the virulence of the organism becomes considerably reduced after two or three passages through the economy of the rat, and hence there are limitations to the destroying power of the virus. It is, however, recommended that repeated distributions of cultures should take place, preferably during the breeding season. Dr. Collingridge has arranged for a supply of the culture with a view to test its applicability, and we shall all watch the results with the greatest interest.

With respect to the condition of the Thames it is discouraging to learn that there were many complaints during the hot weather. Although the Corporation of London has no immediate concern with the treatment of the sewage adopted at Barking and Crossness the condition of the river is obviously matter for the port sanitary authority, seeing that the health of an enormous seafaring population is in question. Dr. Collingridge tells us that the methods adopted are adequate to prevent serious nuisance during the greater part of the year, but during the hot weather something further is needed. During 10 days in July the water from London Bridge to Erith, and more particularly between Greenwich and Crossness, was "very discoloured and offensive." Clearly the effluent is carried up by the spring tides a long distance above the outfalls.

Rhythmic Psycho-neuroses and Morbid Impulses.

Dr. C. H. Hughes of St. Louis, editor of the *Alienist and Neurologist*, in a paper which we publish this week on page 1124, calls attention to certain interesting and medico-legally important forms of mental derangement characterised by a morbid rhythmic activity of the brain and grouped by him under the heading "Autopsychorhythmia," or repetition psycho-neurosis. He refers at the outset to a pathetic story of an accountant who in a state of nervous exhaustion and mental confusion was carried to an asylum pitifully exclaiming, "Once one is two, once one is two," the mistaken calculation having ruined him.

Apparently two factors are concerned in the development f such form of mental derangement—viz., a basis of cereral exhaustion or of feeble will on the one hand, and a hythmic recurrence of irresistible morbid ideas or impulses o action on the other. Some cases manifest themselves nder the forms of imperative ideas of a ludicrous, dangerous, r indecent nature which arise regardless of time or place nd cause the sufferer much trouble and anxiety. French bservers have given to this class of phenomena the apt erm "mental obsession." A special variety of this, known s "blasphematory mania," was noticed long ago by VERGA who described it as a form of mental obsession in which the mental impulses took the form of oaths, blasphemies, or ndecent utterances. The term "coprolalia" has since then been proposed by GILLES DE LA TOURETTE to designate this mpulsive and, as it were, explosive ejaculation of oaths and obscene words. It is not a form of insanity to which the wicked and the depraved alone are prone, for young persons brought up and reared in exemplary surroundings—daughters of clergymen and ladies of good birth and breeding—have been not infrequently known to be subject to this form of mental disorder.

The late Professor CHARCOT regarded these impulses, like he *tics* of the neurasthenic, as closely allied disorders: "The *tic*," he said, "is a disorder that is only in appearance material; it is on the other side a psychical disease, for here are mental as well as bodily tics." A less distressing class of the repetition psycho-neuroses includes echolalia and allied conditions, in which there is an irresistible tendency to imitate and to repeat words and gestures. It must be remembered, however, that the condition of rhythmic repetition of acts and of words and phrases has a certain relation to physiological states. In persons with a fine musical ear tunes and musical cadences once heard will sometimes persistently recur in the mind even to the point of weariness. The overworked student of music is prone to suffer from this trouble, and only rest, recreation, and a tonic treatment will cure it. It is easy to see how overwork and mental overstrain will allow this condition to become a morbid one, and how the resulting cerebral irritation, insomnia, and constitutional disturbance will lead the person into the realm of actual mental aberration. These are the cases which early diagnosis and early treatment could prevent from passing into utter mental breakdown. In the borderland which separates sanity from insanity a whole host of semi-morbid conditions are met with which are characterised by tendencies to morbid impulse and repetition. Many of these have been studied and appropriately named; thus we have arithmomania, a morbid tendency to count letters in a word or objects in a room; the *folie du doute* and the *délire de toucher* of French authors, and the *Grubelsucht* or metaphysical mania of German observers. The subject of this last condition asks questions, propounds problems, and suggests doubts *ad infinitum*. Is he theologically inclined, then he reasons in every conceivable way about the creation, angels, or predestination. Was the world created, or did it come by chance? If created, did GOD do it or did he appoint the angels to do it? And if so, why? In a similar fashion the accountant conceives the idea that his books are inaccurate, he spends hours in seeking for a possible error, is never satisfied that his figures are correct, and is finally obliged to give up work owing to the danger of mental breakdown. The will is primarily feeble in these persons or has become enfeebled by disease, and ideas arising in the mind run their course unchecked. In some patients the morbid impulses towards words and deeds have their starting-point in dream states and run their course in the waking state. This is especially so in alcoholic subjects.

Dr. HUGHES calls attention to a significant group of symptoms which may be the warning of a threatened mental attack—viz., absent-mindedness, abstraction, and a condition which, since its description by the late Dr. W. B. CARPENTER, has been called "mental automaticity." Such symptoms signify little unless they are progressive or indicative of disregard towards the decencies and proprieties of life. If associated with excesses of sexual or alcoholic nature they should always cause suspicion and the mental condition of the patient should then be looked into closely. In some persons inquiry reveals the fact that for years a struggle has been going on between the normal self and morbidly recurring obsessions and impulses. Impulses to acts of the nature of murder, arson, and rape have been known to exist for years and to have been fought against with prayers and struggles. The persistence and recurrence of such internal conflicts eventually produces mental exhaustion; and on a basis of such exhaustion hallucinations and automatic acts may develop. The underlying cerebral condition is twofold—viz., a weakening of the psychical inhibitory functions and an over-action of certain sensorial areas. In every case there is more than a mere motor or kinæsthetic involvement. The disease is therefore a complex one and demands the utmost care and skill in treatment.

Recreative Reading.

THERE will be found in another column a letter from a retired member of the medical profession asking to have the names of good novels recommended to him. The request is one that we have never had made to us before and we should be very embarrassed if we thought that it came within our scope to give him an answer. His statement that he is familiar with certain accepted classics debars the suggestion to him of any of those prose works of imagination which are the chief and peculiar glory of English literature; while the absence of all limitations in his request—of all hint as to the style, the school, and the date that he would prefer—renders it impossible to select for him from the usual grade of popular fiction any group of books that would be especially likely to suit his taste. But while we have been unable to give our correspondent any practical help, he has our best sympathy in his desire to drink in his retirement from a sweet well of enjoyment which he has hitherto left untried; and not only our sympathy but our envy. The hours that he has before him making the acquaintance of LEVER'S and OUIDA'S guardsmen, MARRYAT'S post-captains, BRADDON'S and COLLINS'S villains, AUSTEN'S nubile heroines, and TROLLOPE'S troubled clergy—we omit reference to the accepted classics—will be some of the pleasantest that he has ever spent.

We do not, however, advise medical men to leave all light reading until the time of retirement from active work has come. On the contrary, no man needs recreative reading more than the busy medical practitioner or is more likely to derive from it valuable intellectual distraction. The absorbing character of medical work and the scanty leisure of medical life are alike inimical to the cultivation of tastes and accomplishments which call for prolonged application. Here and there a medical practitioner is an expert musician, a poet and one or two novelists have their places upon the current Medical Register, and several well-known surgeons have shown that it would have been within their power to earn a position as artists had not previous predilections led them to surgery. These men are, however, exceptions to the rule, while they do not necessarily remain constant to their professional career. The rule for medical men is not to find much time for the cultivation of the arts, which makes it particularly valuable to them not to neglect any opportunity which may present itself. And the most obvious opportunity is to use a portion of their scanty leisure in the study of good literature outside purely professional lines. The daily duties of the average practitioner involve little reading, so that he can, if he can make the time, find reading exactly the relief which his monotonous life calls for. The barrister, the clergyman, and, of course, the literary man—callings which make up between them with the medical man what may be termed the learned professions—have constant recourse to books. Books are no change to any of these save to the medical man. And although it is notorious that the *littérateur's* idea of recreation is to read a book, it is equally obvious that for medical reasons he would be much better employed anyhow else, even in playing ping-pong; but to the medical man, especially to the hard-worked general practitioner, books which deal with phases of life outside his daily routine appeal with extraordinary freshness, inasmuch as an opportunity for reading them occurs with such little frequency.

We have no intention of suggesting a choice of recreative reading. The terrible nonsense that was written at the time when certain of our lay contemporaries were discussing the merits of the best 100 books would deter us from making any such attempt, even if we felt that the post of literary adviser to the medical profession were one to which we could aspire, which we do not. The mental attitude and intellectual needs of individuals are as varied as their physical features and cannot be adequately met by any process of arbitrary selection. History, philosophy, poetry, and fiction have each their place in recreative reading and their value cannot be adjudged in accordance with any abstract or artificial standard, but must vary with the intellectual tastes of the reader and with his literary grasp. Many thoughtful men hold that more abiding satisfaction, more true solace from the troubles of the day, can be obtained from the repeated study of some great classic than from the perusal of the ephemeral literature of the day. We think that this is as obvious as it is true, but it does not get over the difficulties that everybody is not agreed as to what is a masterpiece, while everybody does not want to read masterpieces without a break. There is room for the occasional reading of books which, though they are not and never will be classics, give cause for thought or distract the weary mind. The well-read man, the man who is soundly acquainted with great literature, will very generally be able to point out that the good things in any new book are evolved from, derived from, or founded on the good things written by old masters. But the modern way of putting a good thing, by its very modernity, may make the good thing more convincing. To despise a book because it is new is as silly as it is to read nothing but trash because it is new.

Annotations.

"Ne quid nimis.

QUEEN VICTORIA'S NURSES' ENDOWMENT FUND.

THE trustees of Queen Victoria's Nurses' Endowment Fund in a letter to the press appeal very powerfully for an adequate endowment "once for all" of the Fund. Our readers probably know that this Fund originated in the sum of £70,000, the jubilee offering made by English women to Queen Victoria, which was handed over with characteristic benevolence by Her Majesty to "Queen Victoria's Institute for Nurses," the object of which is to train nurses to attend the sick poor in their own homes. Her Majesty took the greatest interest in the work and in the nurses who were trained in the institute. The trustees tell us that there are now 900 Queen's nurses nursing the poor in their own homes in all parts of the United Kingdom, and if only sufficient funds were forthcoming no town or district would be without a nurse. The memory of the Queen is secured in many ways, but in none more appropriately or benevolently than by this Fund, the object of which expresses that element of human tenderness which has endeared her to her own people and to all other peoples in the world. The trustees are a thoroughly representative body and may be trusted to see that no distinctions of creed shall interfere with the help offered by the society to those whose poverty and sickness make them fit objects for its benefits. They tell us that the nurses will have to be multiplied threefold before the work of the Fund is complete. We heartily commend the appeal. Nothing emphasises the kindliness of Queen Victoria's nature more than the foundation of this Fund, and nothing can honour her memory more than a generous response to the trustees. Subscriptions may be sent to Mr. Howard Morley, honorary treasurer Queen's Nurses' Endowment Fund, 64, Cannon-street, E.C.

SWEETS SPARKLING WITH GLASS.

THE production of modern sweets is undoubtedly a fine art judging from the innumerable varieties made and the countless ways in vogue of making them attractive. At one time the most deplorable practice prevailed of employing such poisonous substances as chromium, lead, copper, or even mercury and arsenic, as colouring agents in sweets. Mainly, however, owing to the disclosures of THE LANCET Analytical Sanitary Commission in 1854, the use of such objectionable colouring agents became happily obsolete, and, speaking generally, modern confectionery is now pure. According to our laboratory experience of recent years we have not found any objectionable ingredients of this character in sweets. True, the colouring agent is often an aniline dye, but so great is the tinctorial power of such dyes that it is probable that several pounds of the sweets would contain at most a few grains of the dye and then the dye may be erfectly harmless. It is satisfactory to state that many sweets are coloured with vegetable colouring, such as the chlorophyll of spinach, known as spinach-green, which is now made in large quantities for many commercial purposes. So far this account of modern sweets is satisfactory, but a somewhat unexpected and most objectionable method of manipulating sweets has just been brought to our notice. Sweets are made to glitter by means of splinters of glass, so that the sweet has the appearance of sparkling crystal sugar. We have in our laboratory at the time of writing some specimens of even high-class confectionery, said to be of French make, which all contain a liberal sprinkling of glass splinters. When the sweet is dissolved in warm water the splinters tumble to the bottom of the fluid into a miniature heap of broken glass. The splinters present both sharp points and sharp edges which are eminently calculated to cause an injury to the walls of the digestive canal. It is difficult to imagine a more powerful mechanical irritant than jags of glass which might easily cause laceration and hæmorrhage, not to mention other disturbances such as are set up by foreign bodies less jagged than glass in the alimentary canal. The sweets to which we have referred were sent to us by a correspondent with a request for analysis, and he relates that these sweets were partaken of by two little children who shortly afterwards suffered from severe abdominal pain, in the one case in the region of the appendix. The pain persisted for several days. The effect of sharp glassy particles lodging in the appendix could, of course, be easily disastrous. Our analysis enables us to say most positively that these glittering particles are glass. They are quite unchanged in boiling water or in boiling acids and melt into beads at a red heat. On analysis we obtained silica, lime, soda, and a little lead, which are the constituents of common glass. From their appearance on the sweets the flakes might easily be taken for gelatin or mica. The glass is probably prepared by crushing glass bubbles. It is said that the practice of employing glass in this way for decorating confectionery is extensively resorted to, especially by French makers. The sale of such sweets should render the seller liable to heavy penalties or, better, to incarceration, for broken glass may act exactly as an irritant poison and is most injurious to health. We trust that the Local Government Board will give attention to this matter in order that the local authorities throughout the country may by means of the machinery of the Food and Drugs Act institute practical inquiries and stop the sale of such dangerous articles. It is probable that the practice is adopted in order to compensate for the absence of any crystalline appearance in glucose which is now so much used as a substitute for cane sugar in confectionery. In such a case the practice is not only monstrous because it is likely to lead to serious injury to health, but because it is a fraud also. Sanded sugar was bad enough, but to put glass splinters in sweets is diabolical.

THE BRITISH SCHOOL IN ROME.

"AN Italian Contributor," under date, Rome, April 12th, writes: "Medicine with her sister faculties of law and divinity was duly represented in the brilliant gathering assembled yesterday in the Palazzo Odescalchi to launch the British school and, metaphorically speaking, to break a flask of 'bottled sunshine' over its bows. Lord Currie, His Majesty's Ambassador at the Court of the Quirinal, presided and the company included the Archbishop of York, the heads of the German, French, Austrian, and American archæological schools respectively, Mr. H. F. Pelham, President of Trinity College, Oxford, and Camden Professor of Ancient History in the University of Oxford; the Cavaliere Lanciani, Professor of Roman Topography at the Sapienza; the Commendatore Boni, Excavator-in-Chief of the Forum Romanum; the Contessa Lovatelli-Caetani, the accomplished archæologist representing the Royal Academy of the Lincei; and a numerous attendance of graduates from the Universities of Oxford, Cambridge, Edinburgh, Aberdeen, and St. Andrews. Lord Currie briefly indicated the origin and aim of the school, and paid a well-merited and loudly applauded tribute of praise to Professor Pelham, the chief promoter of the school and chairman of the Executive Committee. Professor Pelham followed with a happy reference to the importance, the interest, and the fascination of the studies now for the first time accessible to the British student in a duly constituted and equipped British school, and after him came Professor Eugen Petersen, first secretary of the Roman Branch of the Deutsches Archäologisches Institut, and the Abbé Duchesne of the École Française, to extend the right hand of fellowship to their young rival. The speeches, all of them happy in tone and cordial in expression, had their appropriate sequel in the conversazione which followed as the company dispersed through the rooms or lingered over the well-provided buffet. Particularly gratifying to the medical contingent was the library with its assortment of books appealing specially to the student of the healing art in its historical aspects—Hippocrates being represented in the great editions of Littré and Ermerins and Celsus, in those of Milligan, Des Etangs and De Renzi, supplemented by Matthioli's fine commentary on Dioscorides and by De Renzi's Collectio Salernitana in five handsome octavos. Medical archæology, indeed, stimulated and aided by the British schools at Athens and in Rome, may now look forward to rich accessions to its treasure-trove, the methodical arrangement of which at either school and its adequate description by the local expert cannot but add interest and attraction to many a 'Physician's Holiday.' The names of men of light and leading in the profession—Arbuthnot, Mead, Heberden, and Gregory, and the more recent ones of J. Y. Simpson, Francis Adams, B. W. Richardson, and Henry Acland—recur to the mind as those of ardent students of the medical past who would have envied their latter-day successors the opportunities and facilities open to them, and whose spirits may well be imagined to look down approvingly on the new adjunct to their favourite studies so auspiciously inaugurated in the British school in Rome."

DOWLING *v.* DODS.

IN another column will be found an appeal signed by various well-known members of our profession, asking medical men to assist Mr Louis Ferdinand Dods to pay the heavy costs to which he was put in defending himself in the action for libel brought against him by Miss Agnes Dowling. It may be remembered that in the original action a jury required Mr. Dods to pay £100 damages to Miss Dowling, but on appeal judgment was set aside and a new judgment was given for Mr Dods with costs, the later result being obviously in accordance with the justice of the case. These costs Mr. Dods has been unable to recover from Miss Dowling, and he finds himself liable for a sum of over £400 We have already laid before our readers details of the case[1] but we may shortly recapitulate them here. Mr. Dods, having the behaviour of Miss Dowling brought to his attention, wrote a letter to the relieving officer of the Paddington district to the effect that to the best of his knowledge and belief Miss Dowling was of unsound mind. The relieving officer revealed the contents of the letter and Miss Dowling brought an action for libel against Mr. Dods. At the trial Mr. Dods's letter was held to be privileged, but the jury found evidence of malice and of want of reasonable care on his part. They also found that he had not spoken correctly in saying that the plaintiff was of unsound mind and that it was not true that she would be a source of danger as a dispenser, but that it was true that she had hallucinations. They gave their verdict for Miss Dowling, awarding her £100 as damages. Miss Dowling certainly had hallucinations, and hallucinations of a pronounced sort. Thus she charged a lady with taking her soul from her by diabolical practices, and she admitted in court that being in Ireland she distinctly heard the voice of a Dr. Groves, who was at the moment in the Isle of Wight. How a dispenser liable to such flights of imagination could be other than a source of danger to those for whom she dispensed we cannot imagine, and it seemed amazing to us that a medical man should be fined for taking steps in the exercise of his profession to prevent an unfortunate sufferer from damaging herself and the public. The second trial reinstated Mr. Dods in public opinion, showing the jury to have taken a hasty view, but, unfortunately, he still remains out of pocket. He was, of course, in the first instance fighting for his own hand, but he has really maintained battle for the whole of the medical profession in a disagreeable situation where, in the present state of the law, any of our readers may find themselves to-morrow. Therefore we ask our readers to give to the appeal published on page 1161 of this issue their best attention. Times are hard and the claims on the purses of the profession are heavy. But Mr. Dods has been severely fined for doing what he conceived to be his public duty and professional fraternity should see that his loss is made as light as possible.

---

[1] THE LANCET, June 23rd (p 1812) and Nov. 10th (p. 1352), 1900.

BICYCLING IN LONDON.

FEW people, probably, except those whose work lies in hospitals realise what a large number of accidents occur daily through the use of bicycles in the streets of London. The daily press has knowledge, generally speaking, only of fatal accidents with their subsequent inquests, and the numerous cases of less serious injury escape the publicity of those papers even whose fortune so largely lies in the misfortune of others, if we may judge by the prominence which their columns give to anything of the nature of accident or tragedy. This lack of information on the part of the daily paper as regards bicycle mishaps provides a rare instance in which the absence of publicity may be deplored. In our opinion the bicycle in London is too freely used for the common welfare, and if the public generally were more fully alive to the accidents to which it gives rise its prevalence in metropolitan thoroughfares would probably diminish. We are second to none in recognising the benefits of most forms of athletic exercise and in appreciating the bicycle as placing a convenient means of muscular exertion before those who without it would be often physically idle. The medical profession, as a whole, has blessed the wheel with a wide approval, and the general opinion has had our support before now, but we maintain that there is a wide difference between bicycling for health and pleasure and riding amidst the kaleidoscopic probabilities of collision in a crowded London thoroughfare. In the first place, the value of the exercise itself is largely discounted by the fact that to ride at all fast is simply to court disaster. Even without the chance of accident from tributary thoroughfares, the traffic of a main route by its intricate packing and sudden halts, by its erratic cabs suddenly turned in obedience to a hurried whistle, by its swaying 'buses stopped at any moment, by its flurried ladies crossing at a wrong time, by its children, and by its dogs, places the bicyclist who rides fast in the imminent risk of a "spill" or a collision in which he or his machine or both will be lucky to escape with a mere fracture. The man or woman who rides fast in London is not likely to be troubled with "nerves," but there is another side to the question which affects the careful rider. He, or more especially she, is in a constant state of nervous tension. Her eyes must comprehend all that is before and on either side of her and her ears must be alive to everything behind. Her brain reels with a constant succession of hurried impressions, and through it all she must keep calm control of every muscle or her equilibrium will reel too. The concentration thus demanded of the London bicyclist has even been the very reason of its recommendation as a "nerve-tonic," and we know an enthusiastic physician who went so far as to declare that to get the fullest effect a person should ride on the wrong side of the road! The chief effect likely to be thus obtained is a short rest in the accident ward of a hospital. For young men accustomed to the prompt actions of athletic games, bicycling amidst the traffic of London may afford a sport or an exercise the risks of which are only enough to make it pleasantly exciting. For older people and for all women we believe the risks outweigh the advantages. Moreover, there are conditions under which no one should run risks. When the roads are greasy, when rain has fallen enough to make wood and asphalt sticky without making them sloppy, anyone who bicycles amidst traffic, unless necessity compels him to, takes an unwarrantable risk. He will often be so placed that the least slip puts his wheel under that of some heavy vehicle and as he leaps off his saddle into the slippery road it is mere luck if he does not fall beneath another wheel. To those who would ride in London when the roads are not properly dry, and to women who would shop on bicycles, we unhesitatingly proffer *Mr. Punch's* historic advice, "Don't." Let the Londoner who wishes to bicycle rise early and do so before the traffic of the day has begun or let him wheel his machine to one of the parks. In either case he will take exercise without risk and will breathe fresh, unpolluted air not to be obtained from the dust-laden atmosphere of crowded thoroughfares.

A CASE OF TOTAL EXTIRPATION OF THE STOMACH.

IN the *Deutsche Medicinische Wochenschrift* of April 11th Dr. A. von Bardeleben of Bochum in Westphalia publishes an account of the case of a woman, 52 years of age, whose stomach he removed in the Augusta Hospital in that town on August 28th, 1900, and whom he showed at a meeting of the Surgical Association of the Lower Rhine and Westphalia held in Bochum on Dec. 8th following. For a year previously to the operation she had suffered from pain in the stomach accompanied by nausea and eructation but without vomiting. Her appetite failed entirely, she lost 40 lb. in weight, and could only hold herself up with a great effort. A moveable tumour of the size of a fist could be felt to the left of the umbilicus. On opening the abdomen the whole anterior wall of the stomach from the cardia to the pylorus was found to be greatly thickened and densely infiltrated. The œsophagus was thereupon divided below a temporary ligature placed close to the diaphragm and the stomach, inclusive of both cardia and pylorus, was removed with detachment (*Abtrennung*) of the great and small omentum. The orifice of the duodenum was sutured, and the end of the œsophagus was attached laterally to the small intestine some distance lower down. The operation lasted 75 minutes, including disinfection, 20 grammes (three-quarters of an ounce) of chloroform being used. The subsequent course of the case was quite uneventful. On the evening of the day of the operation the patient drank a glass of claret, and all rectal alimentation was discontinued after the third day. The food taken thereafter was limited to eggs and soup to which peptonised meat and hydrochloric acid were added. In the second week this was supplemented by potato soup, grated ham, and the like, and the patient got up on the fourteenth day, after which her appetite increased. The first motion of the bowels, which was passed on the fifth day, was quite free from biliary colouring matter, but the second and all subsequent motions were of the normal colour. After leaving bed the patient's weight increased from 67 lb. to 84 lb. The orifices of the stomach after removal included obvious portions of the œsophagus and the duodenum. Microscopical examination showed the tumour to be colloid cancer (*Gallert-carcinom*). Dr. von Bardeleben appends a list of surgeons who have recorded cases of total extirpation of the stomach, the names being as follows: Hemmeter, Brigham, Nolle, Faure, Schlatter, Panchel, Leersum and Rotgans, de Carvalho, and Boeckel. With regard to the case of Professor Schlatter he quotes THE LANCET of Nov. 19th, 1898, page 1314, and with regard to that of Dr. Vieira de Carvalho THE LANCET of Sept. 15th, 1900, page 798.

A WATER COMPANY DIRECTOR ON CISTERNS.

THE last half-yearly meeting of the shareholders of the East London Waterworks Company was held on April 4th, when Mr. Frederick Tendron, chairman of the Grand Junction Waterworks Company, expressed his views on cisterns, of which he advocated the use. According to the *Times* report of his speech, "there ought," he maintained, "to be a moderate-sized cistern in every house, although *cistern water ought never to be drunk.*" (The italics are ours.) "If there was one thing more than another that should be insisted upon," he continued, "it was that in every house a tap shall be fitted on the rising main so that the water which was hourly being renewed should be drunk fresh from the main." As a matter of fact, unfortunately, both the Lambeth and the East London companies have at certain periods during the last few years not hourly renewed the water in their mains. Let us suppose for a moment, for the sake of argument, that Mr. Tendron's statement was strictly accurate. If the water were hourly renewed in the mains, and if, moreover, water from a cistern ought never to be drunk, on what reasonable ground does Mr. Tendron recommend the reinstatement of the domestic cistern?

THE PLAGUE IN SOUTH AFRICA.

WAR and pestilence have frequently been contemporaneous, only as a rule the latter is a consequence of the former. The present epidemic in South Africa, however, appears to be unconnected, at any rate directly, with the war. In Cape Town the usual difficulties have to be faced which are always present in the case of a town containing a population of varied nationalities, races, and creeds. In such a case, religious and other scruples make the work of isolation and other measures necessary for the public safety hard to carry out. With regard to the disinfection and cleansing of houses Dr. Gregory, the chief medical officer, has issued explicit instructions to his staff. Yards, drains, fowl-sheds, and other outbuildings are to be drenched with a solution of corrosive sublimate. Houses are to be first closed and then fumigated with formalin. After remaining 12 hours they are to be aired and sunned as far as possible. All articles in the house are to be divided into three classes: (1) those that can be disinfected in the house; (2) those that must be burned; and (3) those that have to be sent to the steam disinfector. Furniture and hardware articles are to be disinfected with a solution of corrosive sublimate or with another disinfecting fluid which does not spoil metal articles; walls are to be sprayed with the sublimate solution and stripped. Rat-runs are to be traced and fumigated, while all rats met with are to be killed and their bodies burned. The medical officer in charge is to report upon the general sanitary condition of the house as regards drainage and the like, and is also, at the conclusion of operations, to give a certificate to the effect that the house has been properly disinfected. Concealment of cases, as in India, is apparently the great difficulty which the authorities have to contend with. As regards the progress of the disease the latest telegrams state that the matron at the Cape Town plague hospital has died from plague and that on April 17th there were 16 fresh cases recorded.

THE FACTORY GIRLS' COUNTRY HOLIDAY FUND.

ALL rightly applied efforts to promote the health of the poor toilers of our great metropolis deserve hearty support, and the Factory Girls' Country Holiday Fund, of which the Princess Christian is a patron, is the outcome of one of these efforts. Apart from the plea of humanity, the fact that many of the girls who benefit by this fund are engaged in the preparation of food should induce everyone to support the fund, for it is to the benefit of the community as a whole that food should be prepared and stored for future use by healthy operatives. To show the rapid increase of the work done by this institution we may mention that in 1888, when the first report was issued, 39 women and girls received the benefit of a country holiday, while last year 2680 women and girls were sent away from the smoke and grime of their surroundings. This number, large as it is, must represent but a small part of London's poor working girls, and even many of these could not have been sent away had it not been for the kindness of a member of the executive committee who in the middle of last summer advanced £300 when the funds became exhausted. As arrangements have to be made with the cottagers who house these girls some time beforehand it is most desirable that subscriptions should be sent to the honorary treasurer, St. Peter's Rectory, Saffron Hill, London, E.C., early in the spring. That the girls themselves appreciate the efforts made on their behalf can be seen by the letters expressive of heartfelt gratitude which are printed in the report.

THE CORONERSHIP OF THE CITY OF LONDON.

IT is announced that the coroner for the City of London, Mr. Langham, is about to retire after many years' faithful service. Mr. Langham has discharged his onerous duties with conspicuous ability, and we do not fear that we shall be suspected of disparaging his service when we hope that his successor will be a medical man. We have over and over again pleaded in these columns for the principle that the office of coroner should be held by a medical man, but in face of the near approach of this new appointment it will do no harm to recapitulate some of the arguments why a medical man should be preferred as coroner. The office of a coroner is, in the first instance, to decide whether an inquest is necessary—that is to say, he must decide whether a death is natural or unnatural, whether the cause of a sudden death is or is not unknown, and whether a death has or has not been a violent one. These questions can only be answered satisfactorily by an experienced medical practitioner—a most important point. For useless inquests are a grievous infliction upon those who have to act as jurors, while they cause much unnecessary pain to the bereaved relatives. It is argued on behalf of the theory that a coroner should be a lawyer that the coroner has not only to receive evidence but to sift it and to weigh it. But this argument applies equally to the jury and no one has ever proposed that the jury should be composed of lawyers. Moreover, every medical man has daily in the exercise of his profession to weigh evidence received from his patients, from the patients' friends, and from the witness of his own eyes and ears. The viewing of the body is a form when conducted by a lawyer, but when conducted by a medical man the appearance of the corpse may tell him much in support of or against the evidence which will shortly be given before him. To the medical coroner the evidence of friends, physicians, nurses, and eye-witnesses as to injuries or previous illnesses will have a very real meaning, and, in addition, its relation to any undisputed facts before the court will be clear to him in a way that it cannot be clear to persons ignorant of medicine. In a coroner's court the cause of death is not, as in other courts, one issue of a suit—it is the only issue, and the coroner should be a man able to weigh medical evidence and to direct the jury. The value of medical evidence is only completely clear to a man who has had a medical education. We therefore hope that the electors in whose hands the important appointment of the coronership of the City of London rests will appoint as coroner a member of the medical profession.

M. LOUBET AS A SANITARY REFORMER.

SANITARY reformers have found a useful ally in M. Loubet, President of the French Republic. With all the courtesy necessary under the circumstances he has not hesitated to administer a well-merited reproach to the municipality of Toulon. Nothing can be more revolting and scandalous than the insalubrious condition of this town, which still serves as an open door to all the epidemics that can be imported from abroad, while within its walls typhoid fever is in an endemic condition. There are no sewers and no system of drainage; some houses have portable pails, some have cesspools, but a great many houses, even in the centre of the town, have nothing at all, and the inhabitants are content to throw out their night-soil into the streets. On his return from visiting the Italian squadron M. Loubet was entertained by the Municipal Council of Toulon. The Mayor, in his speech of welcome, admitted that for 50 years the necessity of sanitary measures had been recognised, and he asked that the President should use his influence so that something might at last be done. The Mayor, however, did not say anything about a drainage scheme which obviously is the first of necessities. He only spoke of embellishments and of building new and broader streets—schemes that obviously lend themselves more readily to jobbery than the creation of a drainage system. While pointing out that he had no constitutional right to take any initiative in such matters, M. Loubet said that on the strength of his white hair and his services rendered to France and to the Republic for more than a quarter of a century he had authority enough to recommend to the Government that the desire for sanitary reform should be realised and that the Ministers would not dishonour his recommendation. He further urged that the town could well afford to make the effort; that too strict a policy of saving would only cause greater difficulties in the future; and that they ought to put their hands into their pockets and the Government would help them in carrying out a well-matured scheme. By those who are unacquainted with the local history of Toulon the sting of these remarks will not be perceived, but those who are better informed will naturally inquire who is responsible for the present insalubrious condition of Toulon if it is not the present mayor and municipality. Many years ago a scheme for the drainage of Toulon was prepared. This scheme was sanctioned by the Consultative Committee of Hygiene for France, of which Dr. Brouardel is president, and also by the General Council of the Ponts et Chaussées. These two committees are attached to the Ministry of the Interior and represent in France what the Medical and Engineering Departments of the Local Government Board represent in England. Further, the scheme was also approved by a mixed committee representing the Ministries of War, of Marine, of Public Works, and of the Interior. Finally, and from the legislative and administrative point of view, the scheme was confirmed by the Council of State. But at this latter stage a most extraordinary event occurred. According to the law such schemes must be laid before the public of the town concerned and any inhabitant has the right to attend and to bear witness either against, or in favour of, the project. It was now found that the *dossier* containing this testimony had disappeared. It had been lost or stolen from the archives—an incident quite worthy of the Dreyfus case. The Government, tied down by the letter of the law, then insisted that, as a mere matter of form, another public inquiry should be held. This was done, but in the interval a new municipal council had come into power which in the preparing of the scheme had had no finger in the pie. The result of the public inquiry was the same as in the first instance. Out of a population of 104,000, some 1400 persons, including women and servants whipped up for the occasion, had spoken against the proposal. That the scheme is still approved by the great majority of the inhabitants of the town is proved by the recent election of M. Ferrera as representative of Toulon in the Parliament. M. Ferrera was mayor of the town at the time the scheme was accepted, and at the recent parliamentary election the carrying out of the scheme was the first plank in his programme of local reforms. Nevertheless, the present municipality made a pretext of the second inquiry and declared that, in the presence of the results of this inquiry, they would not carry out the project. The contractors who had been engaged for the works are now suing the town. Nine years have been expended over this one scheme. It has received the highest governmental and technical sanction; but because it did not originate with the present municipal majority, all this work, the negotiations, technical reports, &c., which have absorbed so much time, money, and energy are to be destroyed and lost But for these party intrigues Toulon would to-day have possessed a suitable system of drainage. The last two cholera epidemics first made their appearance at Toulon and Marseilles; the latter town has now a general system of drainage. To-day Europe is more or less menaced with the advent of plague, and Toulon is in as bad a condition as it was during the last cholera epidemic. Well might M. Loubet urge the necessity of immediate action, but the bringing forward of a new scheme would mean years of delay.

HÆMORRHAGIC TYPHOID FEVER.

HÆMORRHAGIC typhoid fever—that is, typhoid fever accompanied by generalised hæmorrhages into the skin, mucous membranes, and serous cavities—is rare. The *American Journal of the Medical Sciences* for March contains an important paper on this subject by Dr. A. E. Esbner and Dr. T. H. Weisenberg. In hæmorrhagic typhoid fever hæmorrhage first takes place from the nose and then from the gums. Next petechiæ appear in the skin among the "spots," which become hæmorrhagic only in part, if at all. In severe cases extensive deep-seated extravasations take place into the subcutaneous tissue. In some cases meningeal or cerebral hæmorrhage occurs. There is usually melæna which is sometimes fatal. Hæmoptysis is the least common form of hæmorrhage. The earlier and the more extensive the hæmorrhage the worse the prognosis. The writers report the two following cases. A man, aged 39 years, a heavy drinker, was admitted to hospital delirious on what appeared to be the twenty-second day of his illness. He looked stupid, his tongue was brown and fissured, and sordes were present. The temperature was 103° F. The right iliac fossa was tender. On the chest and abdomen was a rose-coloured maculo-papular rash which disappeared on pressure. The urine contained albumin and blood. The Widal reaction was positive. On the sixth day after admission there appeared on the legs a *symmetrical rose-red* eruption consisting of elevated patches one-eighth of an inch in diameter which did not disappear on pressure. At the same time bluish blotches, from one-eighth to one-quarter of an inch in diameter, which did not disappear on pressure, appeared on the upper chest and shoulders. There were hæmaturia and enuresis. Later in the day intestinal hæmorrhage occurred three times and the hæmorrhagic eruption extended all over the body, the spots being bluish and varying from three-quarters of an inch to one and a half inches in diameter. A hæmorrhage took place into the left cornea. The patient died comatose on the following day. The necropsy showed much blood in the peritoneal cavity, and hæmorrhages in the peritoneum covering of all the abdominal viscera. There were also hæmorrhages into the substance of the latter. The pleural and pericardial sacs contained blood. The bladder contained an enormous clot. In the ileum were five ulcers in various stages. In the second case a man aged 28 years, and addicted to alcohol, was admitted to hospital delirious. The history was that he had been ill for a week. The face was dull and expressionless and the tongue was dry and furred. The urine contained albumin but no casts. The pulse was rapid, weak, and dicrotic, and the temperature was 103° F. A rose-coloured maculo-papular eruption, which disappeared on pressure, appeared. Nervous symptoms became pronounced and carphology and subsultus occurred. The Widal reaction was positive. On the fifth day after admission the tongue was dry, brown, and fissured, and there were sordes. The conjunctivæ were icteric. On the sixth day a dark rusty-red papular eruption, which did not disappear on pressure, appeared on the chest and abdomen. The spots averaged one-eighth of an inch in diameter. Next day the limbs were involved. A peculiar offensive odour was present. Kernig's sign could be elicited. Divergent strabismus and retraction of the head appeared and the patient was extremely restless and exhibited carphology and subsultus. The urine contained albumin and granular and bloody casts. He became comatose and died on the ninth day. The necropsy showed typical typhoid lesions—ulcers ot the ileum and splenic enlargement. The brain and spinal cord showed no abnormality except roughening of the membranes covering the inferior aspect of the cerebellum. The fact that in both these cases of an exceedingly rare complication of typhoid fever the patients were addicted to alcohol *seems to have had no significance for the* writers, but it seems to us of importance, for alcoholism is recognised as a cause of purpura by French writers, though apparently not by American. Typhoid fever *per se* is no doubt capable of producing purpura, but that the alcoholism was a contributory cause in these cases seems probable.

UNQUALIFIED PRACTICE AND DEATH REGISTRATION.

IN order to prevent the danger to the public resulting from medical practice by unqualified persons, and owing to their attention being called to the prevalence of such practice in the urban district of Spennymoor in their county, the County Council of Durham recently made certain representations to the Registrar-General and suggested to him that he should instruct the district registrars of births and deaths to report to the coroners all cases of death not certified by a qualified medical practitioner, so that the coroners might exercise their own discretion as to whether an inquest should be held or not. This after some correspondence the Registrar-General consented to do in respect of the Spennymoor district only on Dec. 1st, 1900, but, strange to say, on Feb. 13th, less than three months later, before the success of the change could be estimated, and without further *reference to the county council, the Registrar-General took* upon himself the responsibility of revoking his own decision and assigned as the cause of his doing so that the delay occasioned in registration caused inconvenience and that no commensurate good had been effected. At a meeting of the county council held subsequently an alderman of the council, who apparently differed from the majority of his fellows in the enlightened view adopted by them, admitted that he and Mr. J. M. Paulton, the Member of Parliament for the division, had interested themselves in the matter, and the influence brought to bear by the Member of Parliament and the alderman no doubt contributed to the rescission by the Registrar-General of his recently issued instruction. We cannot congratulate the official, the Member of Parliament, or the alderman. The last-named, in his speech to the council to which we have referred, as reported in the *Durham County Chronicle* of March 15th, revealed even more interest in the prosperity of the persons practising without qualifications than in the convenience of the miners and others to whom he also referred, while the report of the county medical officer of health, made in last July, is in our view conclusive as to the dangers resulting in the Spennymoor district from the popularity of a certain unqualified person or of certain unqualified persons practising there. In one paragraph it says: "In the urban district of Spennymoor the number of deaths last year which were uncertified as the result of such practice was 77, or nearly 20 per cent of the total deaths, and during the first half of this year these deaths numbered 39, or 25·5 per cent. of the total deaths. During the past quarter there have been two deaths from enteric fever and one from scarlet fever which were uncertified owing to the attendance of an unqualified practitioner, and in none of these infectious cases was any intimation given to the medical officer of health of their existence, and consequently no precautions could be taken to prevent the spread of the disease." We are of opinion that such a state of affairs as that disclosed is alone sufficient to show that *every step* that can lawfully be taken should be taken to compel the production of a certificate of death from a qualified practitioner, and that failing the production of such certificate the coroner should be charged to inquire into the cause of death and to hold an inquest where the cause of death is not absolutely clear or otherwise demands it.

"HAMLET" IN DUMB SHOW.

THE Adult Deaf and Dumb *Institute in Manchester does* very useful work in keeping up a link of association and interest among deaf-mutes scattered over a large area. Some travel great distances to take part in a reunion in Manchester that has now become an annual event. This year it took place on April 6th, and some of the visitors were from Birmingham and others from Scotland At the Hulme Town Hall there was a tea-party in the evening—they are very popular entertainments among some sections of the community in the north—followed by a performance of *Hamlet* by deaf-mutes. Probably the feeling for dramatic representation is as strong in them as in others, but to those who can hear and speak it is difficult to imagine that it can be fully satisfied by signs and gestures, more especially when they are trammelled with the rapid and complicated movements of the finger language. The performance was, however, a great success. Last year the same "actors" gave *Romeo and Juliet*, so that the success was not altogether due to novelty. "The dressing of the play was effective, the scenery was good, and there was spirit in the acting," and "the audience, judged by their attention, felt a real concern in the development and the incidents of the play." It is pleasant to know how cheerfully and successfully these poor folks struggle against the limitations brought about by their affliction, but for all that this silent *Hamlet* must have seemed to the visitor who could hear and speak a pathetic spectacle.

THE JACKSONIAN PRIZE.

THE Jacksonian Prize of the Royal College of Surgeons of England has been awarded by the council of the College to Mr. McAdam Eccles, M.S. Lond., F.R.C.S. Eng., for his dissertation on "The Pathology, Diagnosis, and Treatment of the Diseases caused by and connected with Imperfect Descent of the Testicle."

PUERPERAL INSANITY.

DR. ARTHUR C. JELLY of Boston has published in the Boston *Medical and Surgical Journal* of March 21st an important article on puerperal insanity based upon the medical records of 250 cases of puerperal mental disturbance observed during the years 1872–1900. After referring to the great anxiety and suffering which are caused by puerperal insanity when a young mother becomes suddenly maniacal after the birth of her first child and requires to be sent to an asylum he directs attention to the possibility of prevention. Of the 250 cases referred to above as suffering from puerperal mental disturbance, in 200 the disorder was sufficiently grave to constitute insanity and to require asylum treatment. Cases of the insanity of pregnancy or of lactation were not included, the term puerperal insanity being, somewhat artificially, restricted to those who became insane within six weeks after childbirth. From an etiological point of view two distinct groups were recognised. In the first group the causes were septic infection and exhaustion, complicated in some cases with auto-intoxication. In the second group a psychopathic predisposition existed and the ordinary stresses of the puerperal state were sufficient to cause it to manifest itself in the form of insanity; the puerperal state opened the door and thus the psychosis was, as described by Kraepelin, liberated (*ausgelöst*). Insanity is said to occur once in 460 deliveries. In asylums for the insane from 7 to 9 per cent. of all the female admissions are cases of puerperal insanity. The insanities of pregnancy and of lactation claim each about one-half of the number of victims of puerperal insanity. Dr. Jelly finds a history of insanity, epilepsy, or cerebral disease in one-third of all his cases. Alcoholism also plays an important part, whether it is present as a hereditary taint or as a personally acquired vice. Some patients are liable during the pains and sufferings of childbirth to suffer from suddenly-developed delirious troubles, but these rapidly pass away when delivery has taken place. In such cases a predisposition to epilepsy or profound hysteria often exists in the background (Kraepelin). Illegitimacy is a predisposing cause of puerperal insanity, the latter being twice as common after illegitimate as compared with legitimate births. Cases of puerperal insanity of septic origin have shown a tendency to decline in the last three decades owing to the stricter and wider adoption of antiseptic principles. Thus in the Philadelphia Maternity Hospital 99 cases of puerperal insanity of septic origin were admitted from 1867 to 1877, while from 1887 to 1897 the numbers had fallen to 20, "the latter period being marked by the introduction of stricter antiseptic measures in obstetric practice in Philadelphia." In Boston there has been a decrease in the ratio of puerperal to total labour cases, it being 6 4 per cent. in 1872 to 1880, 4 6 per cent. in 1880 to 1890, and 3·7 per cent. in 1890 to 1900. The more acute septic cases are of short duration and end in death. Others improve after removal of the sources of sepsis, but complete recovery occurs in only a few. The average duration of puerperal insanity is eight months. In some cases where there is marked cerebral exhaustion the patients live only a few days and where recovery takes place the process is slower than in septic cases. Of Dr. Jelly's 200 cases of puerperal insanity 30 had had more than one attack. "One woman was admitted to a hospital for the insane in 1870 with her first attack and in 1899 in her seventeenth attack." In 20 patients some form of mental defect or disorder had existed before pregnancy, thus, one had general paralysis, three epilepsy, three imbecility, three dementia præcox, five delusional insanity, and five secondary dementia. The prognosis as to recovery from a first attack was good (from 75 to 80 per cent.), but the tendency to recurrence was strong and the prognosis was bad after a second or third attack. Treatment consisted in keeping the bowels open, daily catheterisation of the bladder, rest with abundant good food, alcohol and hypnotics in moderate amount so as to secure sleep, and careful guarding against suicide. Home treatment was seldom satisfactory.

SOOT AND TERRESTRIAL AND COSMIC DUST.

IF complexity of composition frees a substance from reproach at all that substance should be soot, for recent micro-spectroscopic analyses have shown that it contains an extraordinary number of metallic elements. Thus chimney soot was found to contain, besides iron and calcium, nickel, manganese, copper, and silver. The soot from laundries seems to contain more elements than that from the kitchen or bedroom chimney, doubtless on account of the more complete combustion of the fuel in the laundry fire. Flue dust, besides containing the more or less common metals such as lead, silver, and copper, contains also nickel and manganese and even rubidium, gallium, indium, and thallium. Gallium appears to occur in all kinds of dusts and soots. Some dusts are clearly of terrestrial origin while others are undoubtedly of cosmic origin. Nickel occurs both in the dust from the clouds (or the dirt in the rain) and in soot, so that its presence in the former is not necessarily an indication of its cosmic origin. The dust which fell upon the earth in November, 1897, yielded a deposit identical with meteoric dust and was magnetic. The dust examined fell on a perfectly calm fine night and there was no rain for upwards of 24 hours. Its composition was totally unlike that of volcanic dust and flue dust from various industrial processes. It was therefore of meteoric origin. It has not hitherto been suggested that when London was in the throes of one of its darkest fogs it was bathed in an atmosphere of rich and rare metallic elements. But such would seem to be the case according to micro-spectroscopic methods. It should be remembered, however, that these methods discover the most infinitesimal quantities; indeed, it may be but a few molecules.

THE spring meeting of the Medico-Psychological Association will be held at the Essex County Asylum at Brentwood on Wednesday, April 24th. From 11.30 A.M. to 1 P.M. there will be an inspection of the asylum and grounds, followed by luncheon on the invitation of Dr. G. Amsden, the medical superintendent of the asylum. At the general meeting, which will take place at 2.45 P.M., Dr. Robert Jones will communicate a paper on "How should the subject of Insanity be taught to the Medical Student?" and Dr. Arthur H. Spicer will deal with "A Case of Spontaneous Fracture." In the evening the members will dine at the Café Monico, Piccadilly-circus.

THE death is announced, on April 13th, of Mr. George Fleming, C.B., LL.D., F.R.C.V.S., late Principal Veterinary

Surgeon to the army. He was born in 1833, served through the Crimea and on the North China Expedition, and was five times President of the Royal Veterinary College. A pathetic circumstance connected with his death is that he died suddenly on the second day after the wedding of his only surviving daughter to Mr. N. S. Manning, F.R.C.S. Irel., of Combe Martin.

THE KING has graciously consented to act as patron of the Prince of Wales's Hospital Fund for London, and His Royal Highness the Duke of Cornwall and York has expressed his pleasure in accepting the office of President in the place of His Majesty the King. His Majesty has intimated that in his capacity as patron he will continue to watch over the work of the Fund with the same deep interes as hitherto.

THE KING, who as Prince of Wales has been President of the Society of Arts since 1863, has now graciously acceded to the request of the society and has consented to become its patron. His Majesty has also permitted the society to continue the use of his profile on the medals of the society.

THERE was a small gathering of the members of the Metropolitan Counties Branch of the British Medical Association at Exeter Hall on April 3rd, when the meeting approved of the principles embodied in the provisional report of the Constitutional Committee.

THE King has been graciously pleased to grant his patronage to the Royal General Dispensary, Bartholomew's-close, E C. His Majesty has also consented to continue his patronage to the Hospital for Consumption and Diseases of the Chest, Brompton.

THE second annual meeting of the American Congress of Tuberculosis will be held at the Grand Central Palace, New York, on May 15th and 16th, in joint session with the Medico-Legal Society of New York.

NOTICE has been received at the Colonial Office, dated April 10th, 1901, that 10 days' quarantine have been imposed at Cyprus against Egypt in consequence of bubonic plague.

THE King has appointed Dr. William Thomas Prout (Colonial Surgeon) to be an Official Member of the Legislative Council of the Colony of Sierra Leone.

DR. H. D. ROLLESTON is starting for Pretoria to replace Dr. J. W. Washbourn for six months as senior physician to the Imperial Yeomanry Hospital.

WORKHOUSE DIETARY.—A man who has been an inmate of Withington Workhouse since August, 1899, has made a practical protest against the new dietary order of the Local Government Board by throwing his breakfast through the doorway and refusing to do any work. He said that it was on account of his health and the insufficiency of the food. On the day of his protest it consisted of one and a half pints of porridge, one and a half ounces of treacle, and two ounces of bread. In addition to the breakfast the paupers, it was explained, if well behaved, had a lunch of bread and cheese. The medical officer of the workhouse said that the man was quite fit to go on the new diet and to do the work allotted to him. Some conversation took place at the county police-court, and the prisoner informed Mr. Yates, the magistrate, that "they give you eight ounces of bread in prison" and that the porridge is very thin and really gruel and "not much good." The medical officer said that "the prisoner seemed to have been put forward as a test case against the new diet." In *sentencing the man* to seven days' *imprisonment* with hard labour Mr. Yates said "he would now be able to compare the two diets."

THE REPORT ON ANÆSTHETICS ISSUED BY THE BRITISH MEDICAL ASSOCIATION AND "THE LANCET" CLINICAL REPORT ON ANÆSTHETICS.

II.[1]

THE sections in the report of the British Medical Association dealing with the methods employed, although of interest, afford no finality in the conclusions which they express. It is pointed out both in this report and in that of THE LANCET that the methods classified under one name may be widely different in their actual technique. A towel or piece of lint employed as a means of exhibiting chloroform may in dexterous hands be tolerably safe, but when used in such *a way as to allow a high percentage vapour of chloroform* with excessive exclusion of air it must result in death. The material upon which the committee of the British Medical Association had to work appears to have been too inexact for them to obtain any very definite results, but some useful information is still to be gleaned from the sections. Thus, although they state that the lint method gives a high danger-rate, higher than the towel method, yet the study of the cases compels the belief that practically all the recorded cases of chloroform administration were those grouped under the general heading of "open method," and that as there were so few figures dealing with any method based upon measured quantities of the anæsthetic used no basis for comparison is afforded. If this contention is correct the figures (pp. 95–96) are really merely those of various *methods, perhaps some superior to others, still all of* them examples of non-regulated chloroformisation. These plans were adopted by a large number of persons some of whom were experts, so that it appears probable that the results obtained constituted a resultant of opposite forces —the careful and the careless chloroformisation.

The two reports emphasise how persistent are the old methods—the "slapdash" methods, as they have been termed. The actual variety of the "open method" employed is thus shown to be of less importance than the individual skill of the person carrying it out. Certain it is, that we possess no statistics which prove the safety or the converse of the "open method," or of the method in which a regulating inhaler is employed. The appendix to the British Medical Association report gives a small number of cases (1521) in which a semi-closed method (the Hyderabad cone), was followed with a death-rate of *nil* and a low danger-rate, but here obviously the surgeon in charge took the utmost care to avoid an overdose. Moreover the plan adopted was to pour measured quantities of the chloroform into the cone at stated intervals, thus giving a certain degree of regulation of dosage by this method. These cases are too few for comparison with the towel, lint, or Skinner mask cases. All methods used for the exhibition of chloroform taken together according to the British Medical Association report, give a complication-rate of 3·27 per cent. to the total number of cases, a danger-rate of 1·032 per cent., and one death in 744 cases; the towel method gives a complication-rate of 3 92 per cent., a danger-rate of 1·41 per cent, and one death in 888 cases, and the lint method gives a complication-rate of 2·14 per cent., a danger-rate of 0 59 per cent., but one death in 542 cases, *showing that* although the cases of danger were few they were extremely grave when they did occur. The regulating method suggested by Dr. Junker and sometimes recorded under other names was only recorded in 411 instances, but although these showed a favourable record it would be useless to base any arguments upon so slender a foundation. Indeed, the experience of the past *years has shown the* tendency there is for an observer after the careful use of one method subsequently to regard his success as necessarily a proof of the value and safety of his plan. The good results are usually due less to such a cause than to the expertness acquired by conscientious employment of a routine method.

It would not only be tedious, but quite useless, to consider methods in the case of other anæsthetics than chloroform. We may, however, remark that the committee call attention, and we *think rightly,* to the fact that when mixtures containing chloroform—e.g., the A.C.E. mixture—are exhibited from closed inhalers the danger-rate is at once greatly increased.

---

[1] Article I. was published in THE LANCET of March 30th, 1901, p. 951.

Germane to the question of method is that of the quantity of the anæsthetic employed. There are two considerations which must be borne in mind in attempting to arrive at any conclusions about what bearing a rapid or a slow rate of evaporation of an anæsthetic may have upon the safety or danger of the method employed. These are (1) whether we are dealing with a uniform evaporation-rate (we believe this is not so in the section, p. 95) and (2) whether a rapid evaporation was associated with a high air dilution. Obviously, until we know that the air dilution is constant or that it varies according to a known rate and that the evaporation is so uniform that we can be sure that the cases of danger were not those in which a high evaporation-rate existed throughout, we cannot learn very much from even the most elaborate tables or collocation of figures. Let us take an example to make this point clear. If a chloroformist adopts a very slow rate of evaporation, the time of induction being prolonged, a great temptation is offered to accelerate the induction of narcosis by rapidly increasing the quantity of the anæsthetic given. In such a case the danger or death would appear in the report before us in association with an apparently small quantity of chloroform distributed over the prolonged induction. As must have been expected the mere rate at which chloroform is inhaled appeared to be a matter of no importance, the vital question being how much air was present to dilute its vapour.

The duration of anæsthesia was also studied and the following deductions from the statistics are certainly of interest, even although it would be unwise to attach too much importance to them since they are unfortunately divorced from such contributory factors as methods of administration, age, and general condition of the patient, the temperature of the room, and, perhaps the most important of all, the character and severity of the operation. The methods, indeed, adopted in the British Medical Association's report, possibly incident to the peculiar circumstances of its conduct, tend to over-specialisation in the sense that many intimate factors are separated and this leads to a serious loss of continuity. Thus besides the instances given above, we meet with "phenomena of anæsthesia" and "after-effects" wholly separated from "general conditions," "nature of operation," "duration of administration," "quantity of anæsthetic used," and method of induction.

Dealing with chloroform, we find that prolonged duration (*vide* p. 85) was marked by a high rate of complication, including many trivial complications such as were included in Class *a*, while the danger-rate was higher in the initial stages of anæsthesia and became markedly less in very prolonged cases—e g., those exceeding an hour; 75 per cent. of the deaths occurred before the average duration of chloroform narcosis was reached (i.e., 22·748 minutes). However fatalities possibly with causal relationship to prolonged anæsthesia are recorded in relation to three cases which lasted 40, 45, and 90 minutes, these being the longest anæsthesia noted. The cases of "danger" which, however, did not lead to death were distributed pretty evenly throughout the period of anæsthesia, being apparently as liable to occur in short, in medium, and in prolonged operations under anæsthetics. These two facts are of great importance as they appear to show that on the one hand the dangers attributed to incomplete anæsthesia, and on the other those arising from operation effects incident to prolonged anæsthesia, did not exist at all events in sufficient number to influence the statistics. The effects incident to incomplete anæsthesia would appear in the early stage and those due to operative shock and exhaustion in the later stage of narcosis, but, as we have said, no clear indication of such is found in the figures before us. When all anæsthetics are taken together the highest danger-rate existed in cases lasting over two hours (2·12 per cent. to the total number of cases), the next highest in those lasting less than five minutes (1·58 per cent.) and then in those lasting between five and 10 minutes (1·0 per cent.). Under chloroform alone the danger-rate was also highest in narcosis lasting less than five minutes (2·02 per cent.); for those lasting from five to 10 minutes it was 1·42 and a slight but not uniform rise followed. The incidence of danger in the early stage of narcosis under chloroform, ether, gas and ether, and the A.C.E. mixture seems to indicate either that the stage of induction is the period of greatest peril or that the tendency is to rush the patient into unconsciousness without due regard to consequences. It may be added that as the "after-effects" phenomena and "imperfect anæsthesia" cannot but be regarded as closely allied to the question of duration of anæsthesia and "quantity of anæsthetic" used, we propose to consider the sections (pp. 106 and 122) in the present connexion.

In Table LXXII. an attempt is made to associate the after-effects with the duration of anæsthesia, but only retching and various degrees of sickness, collapse, headache, excitement are given. That such phenomena should, *cæteris paribus*, occur in prolonged anæsthesia seems to need no comment. Considering the chief after-effects *seriatim* the following facts are stated (p. 108) in the report. While slight (i.e., post-anæsthetic) vomiting occurred in the following order as to frequency after (1) ether, (2) A.C.E., (3) gas and ether, and (4) chloroform, prolonged (severe) vomiting occurred in the following order: (1) chloroform, (2) gas and ether, (3) A.C.E., and (4) ether. In the last case the complication was rare. Circulatory depression occurred most frequently after chloroform, less after ether, and still less after gas and ether, and this in spite of the fact that there is evidence that in many cases ether was selected because circulatory depression was feared. Bronchitis, or bronchial catarrh, is noted as occurring once in every 400 ether administrations, and only once in every 3300 chloroform cases. These cases were grouped as "anxiety," while no instances occur under "danger" or "death." In the 13 cases given two were severe bronchitis, but of short duration, the other 11 being apparently mild and probably merely catarrh of a very transitory character. One case of broncho-pneumonia only was recorded which occurred after A.C.E. in succession to ether and commenced on the fifth day after the inhalation. Corroborative evidence of the extreme rarity of fatal lung complications following the use of ether is given in THE LANCET report, pp. 167 to 173. Of the 37 cases of which necropsies are given only two give evidence of possibly acute lung trouble which may have been related causally with the inhalation of ether. These were a case of "ether pneumonia" and one of pulmonary œdema. On referring to the actual cases we find that three deaths are described as resulting from heart failure due to respiratory embarrassment from emphysema, while in a fourth these conditions were intensified by the presence of bronchitis. It is to be noted, however, that all these conditions were chronic and although the improper use of ether made them dangerous yet they were not the result of ether inhalation. In another case (see Case 1) ether was given to a person suffering from bronchitis and this procedure, most improper in itself, led to an exacerbation of the patient's disease. After noticing the intensification of the symptoms of such complaints as pneumonia, bronchorrhœa, and empyema, the report concludes by saying: "It is noteworthy that comparatively little mention is made of patients dying from pulmonary affections initiated by the ether." And this statement becomes more emphatic when we remember that THE LANCET report covers a period of years from the first use of ether to 1891 and includes a long period during which the methods by which ether was given were not only crude but even dangerous.

Renal after-effects are conspicuously absent as a direct result of ether inhalation. In the British Medical Association report two cases of uræmia are noted, but in neither can the effects of the operation be eliminated. THE LANCET report makes the statement: "In no cases are reliable facts given pointing to nephritic trouble *following* the use of ether." These facts are very striking, perhaps the more so as the first report referred to has shown little tendency to favour ether, at all events in the body of the text.

Both reports again refer in some detail to the question of the relative importance of respiratory and circulatory failure under chloroform, and again they concur in asserting that while the former frequently occurs, yet in the "danger" and "death" cases the latter phenomenon is the one of first importance. Personally, we believe that as our knowledge of the physiology of the subject increases we shall attach much less importance to the point, but at present it seems pretty certain that the weight of evidence tends to show that more patients die from chloroform through circulatory depression, apparently arising from cardiac enfeeblement or vaso-motor paresis or both.

It is with a feeling of regret that we refer to the sections in the report which consider the all-important question of resuscitation. Here we are met by a unanimous verdict of *non possumus*. It is idle beating of the air. We are inclined to wish that some attempt had been made in the report of the British Medical Association, upon the committee of which sat men of great experience, to point out how futile and wasteful of valuable time are most of the measures recorded as having been used in attempting resuscitation. Surely with the knowledge gathered from a review of minor and major complications arising in 26 000 cases some definite directions might have been advanced to help those who in desperate plight strive often without method or system to restore to animation patients over-narcotised or asphyxiated.

The "conclusions" of the British Medical Association report are perhaps the weakest portion of that pronouncement. They exaggerate the timidity of utterance which it appears to us shows itself throughout the whole. In those which are truly conclusions, that is, direct inferences from premisses given before and not merely repetitions of statements of fact, we notice an apparent "hedging," which certainly lessens the value of the report as a guide to practical men. Thus, on p. 124 we read: "Although (excluding nitrous oxide) ether may be accepted as the safest routine agent, certain circumstances, determined by the state of the patient, the nature of the operation, &c., may render the use of some other anæsthetic or combination of anæsthetics both safer and easier." If such a statement means anything at all it amounts to this, that the writers were quite unable or unwilling to give a definite opinion as to the anæsthetic which should be given without adding so many vague generalities as to leave their decision colourless and devoid of merit. The conclusions of THE LANCET report are definite and are borne out by the facts given in the body of that report.

In the general conclusion of the British Medical Association report, although we find some firmness of affirmation, we venture to think that it is diametrically opposed to the findings of the preceding sections of the report. It states in two forms the same thing, that the one thing needful is the experience of the anæsthetist—all other things pale into nebulous nothings beside his overpowering personality. But although we endorse the statement that no one who has not experience or who has not learnt the principles of his art should be entrusted with the care of a patient, yet we fail to see what useful purpose such an elaborate report as that before us can subserve if its 134 pages cannot tell us more than this statement of platitude presents. Surely the experience of even the expert needs supplementing by the views of others and by the study of reports such as those before us, to be broadened by definite statements which may reasonably be looked for from such reports. Unquestionably the main value of the report of the British Medical Association lies in the many sidelights which it perhaps unwittingly throws upon the subject. Its dealings with the phenomena of narcosis and the after-effects, the "complications," many of which appear to the ordinary person almost too trivial to chronicle, are very useful sometimes as guides as to what to do and sometimes as beacons warning against what to avoid. The cases of death, all of which are epitomised, are too few for special comment, and this section is of far less importance to the student than the corresponding portion of THE LANCET report which gives the particulars of practically all fatalities which occurred in a period of over 40 years. No reference in the body of the report of the British Medical Association is made to the appendices, nor are these of special moment. That of Professor Ramsay is somewhat belated, as he had given his views some years back in a leading lay magazine, and although his *dicta* concerning the purification of chloroform by slaked lime have been adversely criticised by experts in chloroform-making, we notice that he has not availed himself of the present opportunity for reconciling his statements with those of his critics. Lieutenant-Colonel Lawrie's appendix is very interesting. It explains his methods and describes his practice, which has become so far modified that he now uses measured quantities of chloroform. The report of the British Medical Association brings into bold relief the leisure, order, and numerical strength of the anæsthetic staff which under Lieutenant-Colonel Lawrie controls the proceedings of the Afzulgunj Hospital.

MESSRS. BAILLIÈRE, TINDALL, AND COX, medical publishers, in consequence of their premises being required for the enlargement of Charing Cross Hospital, have removed to 8, Henrietta-street, Strand.

THE CASE OF MR. LOUIS FERDINAND DODS: AN APPEAL.

WE have been requested to announce that the undersigned gentlemen have formed themselves into a committee for the purpose of assisting Mr. Louis Ferdinand Dods in defraying the heavy law costs and expenses which he has been unfortunately put to (amounting to over £400) in defending the action brought against him by Nurse Dowling for an alleged libel in respect of a notice which he gave to a relieving officer in accordance, as he believed, with the Lunacy Acts.

The appeal of the signatories runs as follows:—

"In the first instance upon the action being tried by Mr. Justice Darling and a jury a verdict was given against Mr. Dods for £100, but happily for the general public and the profession the Court of Appeal put the matter right and reversed the verdict and judgment of the court below and directed judgment to be entered for the appellant with costs, which, however, he has not been able to recover. Looking at all the circumstances, and considering that Mr. Dods has for many months had the severe strain and burden of a litigation which he has concluded so successfully, as much for the benefit of his colleagues in the profession as for himself, the committee earnestly appeal to the medical profession generally, and to all others who may be disposed to be generous, to contribute to the fund."

Mr. W. J. Walsham has consented to act as honorary treasurer and contributions may be sent to him or to any other member of the committee as follows:—

LAUDER BRUNTON, M.D. Edin., F.R.S.,
10, Stratford-place, W.
GEORGE DANFORD THOMAS, M.D. Brux.,
20, Brunswick square, W.C.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on April 13th, the President, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., being in the chair.

Mr. Sibert Forrest Cowell was admitted to the office of secretary and he signed the required declaration.

A letter of March 20th was read from the Home Secretary conveying the thanks of the King for the address of the College expressing sympathy on the occasion of the death of Queen Victoria and congratulation on His Majesty's accession to the Throne.

The Museum Committee reported that a number of Chinese and other skeletons and skulls had been purchased for the museum.

The best thanks of the Council were given to Mr. Bryant for his present to the College of books and pamphlets.

The question of providing additional accommodation for the library was referred to the Library Committee.

The Council, on the recommendation of the committee, did not award the triennial prize. The Jacksonian Prize was awarded to Mr. W McAdam Eccles, the author of the essay on the Pathology, Diagnosis, and Treatment of the Diseases caused by and connected with Imperfect Descent of the Testicle, with the motto "*Crux mihi grata quies.*"

The subject for the next collegial triennial prize was chosen—"The Pathological Conditions arising from Imperfect Closure of the Visceral Clefts."

The subject for the next Jacksonian Prize for the year 1902 was chosen—"Fracture of the Skull: its Consequences, Immediate and Remote, including Pathology and Treatment."

In future it will be required that all essays for the collegial triennial and Jacksonian prizes shall be typewritten.

On the recommendation of the Walker Prize Committee it was resolved not to award the prize on this occasion. The opinion of the committee was arrived at after consulting, and receiving most valuable advice and assistance from, eminent French, Italian, German, Scandinavian, American, Canadian, and British surgeons and pathologists.

The following two Members of the College of 20 years' standing were elected to the Fellowship: Mr. Priestley Smith of Birmingham and Major Ronald Ross, I.M.S., of Liverpool.

A report from the Board of Examiners in Dental Surgery was received, but it was referred back to the board for further consideration in connexion with other matters.

Dr. T. G. Brodie was re-elected Superintendent of the Laboratories subject to the approval of the Royal College of Physicians of London.

It was resolved to ask the Royal College of Physicians of London to appoint delegates to meet delegates of this College for the purpose of considering the position of the two colleges with regard to the reconstituted University of London.

In reply to a letter from the secretary of the Congress on Tuberculosis requesting the loan of specimens from the museum it was referred to the chairman of the Museum Committee and the Conservator of the Museum to select the specimens to be lent.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6177 births and 4339 deaths were registered during the week ending April 13th. The annual rate of mortality in these towns, which had been 18·4, 19·7, and 19·2 per 1000 in the three preceding weeks, was again 19 2 last week. In London the death-rate was 18·3 per 1000, while it averaged 19·8 in the 32 large provincial towns. The lowest death-rates in these towns were 11·2 in Croydon, 11·6 in Cardiff, 12·3 in West Ham, and 15 7 in Birkenhead; the highest rates were 23·7 in Newcastle, 23·9 in Preston, 24·2 in Manchester, and 25 0 in Liverpool. The 4339 deaths in these towns included 397 which were referred to the principal zymotic diseases, against 427 and 380 in the two preceding weeks; of these, 130 resulted from whooping-cough, 112 from measles, 68 from diphtheria, 35 from diarrhœal diseases, 31 from scarlet fever, 19 from "fever," and two from small-pox No death from any of these diseases occurred last week either in Plymouth or in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Brighton, Norwich, and Blackburn, and the highest rates in Portsmouth, Bristol, Wolverhampton, Liverpool, and Burnley. The greatest proportional mortality from measles was registered in Portsmouth, Liverpool, Leeds, Hull, Sunderland, and Gateshead; from scarlet fever in Derby; and from whooping-cough in Bristol, Swansea, and Wolverhampton. The mortality from "fever" showed no marked excess in any of the large towns. The 68 deaths from diphtheria included 26 in London, five in Bristol, five in Leicester, four in Birmingham, and four in Manchester. Two fatal cases of small-pox were registered last week in Liverpool, but not one in any other of the 33 large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums hospitals on Saturday, April 13th, The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1601, against 1568 and 1572 on the two preceding Saturdays; 205 new cases were admitted during the week, against 151, 167, and 180 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 363 and 360 in the two preceding weeks, further declined last week to 345, and were 45 below the corrected average. The causes of 66, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Salford, Bradford, Leeds, Hull, and 10 other smaller towns; the largest proportions of uncertified deaths were registered in Norwich, Liverpool, Blackburn, Preston, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·1, 21·6, and 24·1 per 1000 in the three preceding weeks, declined again to 23·2 during the week ending April 13th, but showed an excess of 4·0 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16·8 in Perth and 18·9 in Leith and in Paisley to 23·9 in Edinburgh and 24·1 in Glasgow. The 726 deaths in these towns included 51 from whooping-cough, 17 from measles, 13 from diarrhœa, six from small-pox, four from diphtheria, three from scarlet fever, and one from "fever." In all, 95 deaths resulted from these principal zymotic diseases, against 87, 93, and 102 in the three preceding weeks. These 95 deaths were equal to an annual rate of 3·0 per 1000, which was 1·2 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 36 and 57 in the two preceding weeks, declined again last week to 51, of which 27 occurred in Glasgow, 10 in Edinburgh, six in Dundee, and four in Paisley. The deaths from measles, which had been 17 and 16 in the two preceding weeks, rose again to 17 last week, and included 10 in Edinburgh, three in Glasgow, and two in Leith. The fatal cases of diarrhœa, which had been 16 and 8 in the two preceding weeks, rose again last week to 13, of which six were registered in Glasgow, four in Aberdeen, and two in Dundee. The deaths from small-pox, which had been 24, 11, 10, and five in the four preceding weeks, rose again to six last week, and all occurred in Glasgow, where the four fatal cases of diphtheria were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 126, 127, and 150 in the three preceding weeks, further increased last week to 155, and showed an excess of 21 over the number in the corresponding period of last year. The causes of 32, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 36·6, 34·0, and 31·9 per 1000 in the three preceding weeks, rose again to 35·6 per 1000 during the week ending April 13th. During the past four weeks the death-rate in the city has averaged 34·5 per 1000, the rates during the same period being 18 0 in London and 22·4 in Edinburgh. The 236 deaths of persons belonging to Dublin registered during the week under notice were 24 in excess of the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against 14 and 12 in the two preceding weeks; of these, eight resulted from whooping cough, three from diarrhœa, 2 from scarlet fever, and two from "fever." These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rates during the same period being 1·9 in London and 3·9 in Edinburgh. The fatal cases of whooping-cough, which had been seven, 11, and five in the three preceding weeks, rose again last week to eight. The mortality from diarrhœa showed a slight increase over that recorded in the preceding week. The fatal cases of "fever," which had been two, one, and four in the three preceding weeks, declined again to two last week. The 236 deaths in Dublin last week included 37 of children under one year of age and 59 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Six inquest cases and four deaths from violence were registered; and 79, or one-third, of the deaths occurred in public institutions. The causes of 15, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 29 cities and boroughs in the county of London. With

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MARCH, 1901.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1901.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles.	Scarlet fever.	Diphtheria.†	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœal diseases.	Total.	Annual rate per 1000 persons living.

* Including 19 cases of membranous croup.

† Including deaths from membranous croup.

regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·2 per 1000 of the population, estimated at 4,651,113 persons in the middle of the year. In the three preceding months the rates had been 8·0, 6·2, and 5·7 per 1000 respectively. The rates were considerably below the average in the City of Westminster and in Hampstead, Holborn, Battersea, and Wandsworth boroughs; while they showed the largest excess in Fulham, Poplar, Bermondsey, Camberwell, Deptford, and Lewisham. One case of small-pox was notified last month in Fulham, but not one in any other metropolitan borough; and no small-pox patients were under treatment in any of the Metropolitan Asylums hospitals at the end of March. Scarlet fever was slightly less prevalent during March than in the preceding month; among the various metropolitan boroughs this disease showed the highest proportional prevalence in Paddington, Fulham, Poplar, Southwark, Deptford, and Lewisham. The Metropolitan Asylums hospitals contained 1533 scarlet fever patients on March 30th, against 2460, 1979, and 1791 at the end of the three preceding months; the weekly admissions averaged 142, against 214, 164, and 156 in the three preceding months. The prevalence of diphtheria during March has shown no variation from that recorded in each of the two preceding months; the greatest proportional prevalence of this disease occurred in Fulham, St. Marylebone, Poplar, Camberwell, Deptford, and Lewisham. There were 1084 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1343, 1113, and 1111 at the end of the three preceding months; the weekly admissions averaged 134, against 127, 129, and 136 in the three preceding months. The prevalence of enteric fever last month showed a further decline from that recorded in recent months; among the various metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, Hackney, Finsbury, Shoreditch, Poplar, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 403, 299, and 224 at the end of the three preceding months, had further fallen to 162 at the end of March; the weekly admissions averaged 18, against 51, 32, and 25 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Chelsea, Holborn, Finsbury, City of London, and Bermondsey. Of the 11 cases of puerperal fever three were notified in Shoreditch borough.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the patients had previously resided. During the four weeks ending March 30th the deaths of 6358 persons belonging to London were registered, equal to an annual rate of 17·8 per 1000, against 16·2, 17·5 and 19·4 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 12·3 in Hampstead, 13·7 in Wandsworth, 13·8 in Stoke Newington, 14·9 in Lewisham, 15·2 in Kensington, and 15·5 in Islington; the highest rates were 20·5 in Finsbury, 20·9 in the City of London, 21·4 in Stepney, 21·9 in Southwark and in Bermondsey, and 22·4 in Shoreditch. During the four weeks of March 567 deaths were referred to the principal zymotic diseases; of these, 166 resulted from measles, 30 from scarlet fever, 83 from diphtheria, 198 from whooping-cough, 27 from enteric fever, one from simple continued fever, and 62 from diarrhœal diseases. The lowest death-rates last month from these diseases occurred in the City of Westminster, in Hampstead, Islington, Stoke Newington, Holborn, in the City of London, and in Woolwich; and the highest rates in Hammersmith, Hackney, Poplar, Southwark, Bermondsey, Camberwell, and Deptford boroughs. The 166 deaths from measles showed a decline of 94 from the corrected average number; this disease was proportionally most fatal in Hackney, Southwark, Bermondsey, Camberwell, Deptford, and Lewisham. The 30 fatal cases of scarlet fever were 23 below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Kensington, Fulham, Stepney, Southwark, and Lambeth. The 83 deaths from diphtheria showed a decline of 80 from the corrected average number; this disease was proportionally most fatal in Hammersmith, St. Pancras, Bethnal Green, Poplar, and Camberwell. The 198 fatal cases of whooping-cough were 61 below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease showed the greatest proportional fatality in Kensington, Hammersmith, Chelsea, Shoreditch, Poplar, and Deptford. The 28 deaths referred to "fever" were slightly below the corrected average number; the highest "fever" death-rates occurred in Fulham, St. Pancras, Islington, Holborn, Bethnal Green, Stepney, and Poplar. The 62 deaths from diarrhœal diseases showed a considerable excess over the number in the corresponding periods of the 10 preceding years; these diseases were proportionally most fatal in the City of Westminster, St. Marylebone, Finsbury, Southwark, Lambeth, and Lewisham. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during March was nearly 31 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 130 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Hackney, Holborn, Finsbury, Greenwich, and Woolwich; and the highest rates in Kensington, the City of Westminster, the City of London, Camberwell, and Deptford.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Deputy Inspector-General G. J. Irvine to Chatham Hospital. Staff Surgeons: F. A. Brice to the *Malabar*, for Bermuda Dockyard; G. A. Waters to the *Psyche;* and E. W. Lomas to the *Northampton*. Surgeons: P. H. Boyden to the *Woodlark* on recommissioning, and John Whelan to the *Howe*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. W. Ford is posted to the Station Hospital, Portsmouth, for duty. Lieutenant Henderson is placed under orders for India. Lieutenants A. J. Hull and R. D. Jameson join at Woolwich. Lieutenant-Colonel R. O. Gunning, Acting Principal Medical Officer, North-Western District, is placed under orders for South Africa.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Albert Ehrmann, 22nd Middlesex Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Cinque Ports (Eastern Division, Royal Garrison Artillery): Christopher Ralph Skyrme to be Surgeon-Lieutenant. Renfrew and Dumbarton: Surgeon-Captain W. A. McLachlan resigns his commission. 2nd East Riding of Yorkshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant-Colonel J. Sherburn resigns his commission, with permission to retain his rank and to wear the uniform of the corps on his retirement. *Rifle:* 1st Volunteer Battalion the Lincolnshire Regiment: Surgeon-Lieutenant-Colonel H. Wright resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 3rd Lanarkshire: Alexander Roxburgh to be Surgeon-Lieutenant. 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): George Francis Whyte to be Surgeon-Lieutenant. 5th (West) Middlesex: Edwin Charles Montgomery-Smith to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Lieutenant G. A. Wright resigns his commission.

MENTIONED IN DESPATCHES.

Nigeria.

The names of Dr. F. Cargill and Dr. Thompson are specially mentioned in despatches (the latter for sucking poison from an arrow wound) to the Colonial Secretary relating to the punitive operations in Northern Nigeria.

South Africa.

The following extracts are from a despatch from Earl Roberts, K G., to the Secretary of State for War, dated April 2nd, 1901:—

Royal Army Medical Corps.—Under Surgeon-General Wilson this department has laboured indefatigably both in the field and in the hospitals. Some cases have been brought to my notice in which *officers have proved unequal to the exceptional strain thrown upon* them by the sudden expansion of hospitals, and in the earlier stages of the war the necessity of more ample preparations to meet diseases [illegible] been fully [illegible] no doubt [illegible] am not, [illegible] the great [illegible] *There* are [illegible] been dis- [illegible] der heavy [illegible] been ably [illegible] consulting surgeons who have come out to [illegible] experience materially aided the [illegible] *services rendered by Sir William* [illegible] F. Treves, the late Sir W. Stokes, [illegible] Mr. Kendal Franks, Mr. John [illegible] were of incalculable value. The [illegible] necessitated the employment of a large number of civil surgeons, and to these gentlemen the army owes a debt of gratitude. The heavy strain on the Army Medical Department was further much *relieved by the patriotic efforts of the several committees and* individuals who raised, equipped, and sent out complete hospitals. None but those on the spot can realise how much the Irish Hospital under Sir W. Thomson; the Yeomanry Hospitals and Bearer Co., under Mr. A. D. Fripp, M.V.O., M B., M.S., Mr. A. R. J. Douglas, M.R.C.S., Mr A. A. Scott-Skirving, M R.C.S., Mr. T. H. Openshaw, F.R.C.S.; the Langman Hospital, under Mr. R. T. A. O'Callaghan, F R.C.S.I.; the Welsh Hospital, under Professor T. Jones, M D., F.R.C S. (dead), Professor A. W. Hughes (dead); the Princess Christian's Hospital, under Mr. J. P. Bush, M R.C.S.; the Edinburgh Hospital, under Mr. D. Wallace, M B.; the Scottish National Hospital, under Mr. H. E. Clarke, M.R.C S; the Van Alen Hospital, under Mr. S. Osborn, F.R.C.S.; and the Portland Hospital, under Mr. A. Bowlby, F.R C S—contributed to the comfort and well-being of the sick and wounded.

I might here mention the invaluable assistance rendered to the sick and wounded by those private persons, members of the British Red Cross Society, who, headed by Her Royal Highness Princess Christian, raised, organised, and equipped hospital trains. As a result of their patriotic exertions two complete trains were constructed, one being built at Birmingham and the other made up at East London. Eight other hospital trains were organised by the medical authorities in South Africa, and also rendered excellent service. It may give some idea of the work which was accomplished by these trains if I append a statement showing the distance they covered and the number of patients they carried:—

Cape Line Railway.

—	Journeys.	Miles.	Patients.
Second train	126	67,000	6,063
Third "	64	62,000	6,238
Fourth "	24	Unknown.	2,683
Fifth "	26	28,200	3,113
Sixth "	31	Unknown.	2,694
Seventh "	92	"	6,296

Natal Line Railway.

—	Journeys.	Patients.
First train	145	12,148
Second "	166	12,789
Third "	9	732

Hospital Ships.

The army in South Africa owes a great deal to the hospital ships and to the staff of medical officers and nurses who attended the sick and wounded, transferred to them from the base hospitals.

The *Spartan*, *Trojan*, [illegible] invalids to Cape Town [illegible] *Dunera*, *Orcana*, *Avoca* [illegible] transports and were fitte[illegible] a fortnightly system of [illegible] England [illegible] and men

The following table will be of interest:—

Name of ship.	Where prepared.	By whom.	No. of voyages home with invalids up to end of December, 1900	No. of invalids carried.
Spartan.	Southampton.	Union S.S. Co.	1	108
Trojan.	"	"	1	66
Princess of Wales.	Newcastle-on-Tyne.	Messrs. W. Armstrong, Whitworth and Co.	3	526
Maine.	Thames.	Atlantic Transport Company.	2	285
Lismore Castle.	Durban.	Admiralty Transport Department.	2	289
Avoca.	"		4	1131
Dunera.	"		2	639
Orcana.	"		3	548
Nubia.	"		2	543
Simla.	"		3	816

My thanks are due to Khem Bahadur Dhanjibhoy, a Parsee gentleman long resident in the Punjab, who presented tongas for ambulance purposes. These tongas were horsed and fully equipped with drivers and all necessary gear. These proved most useful.

Nursing Sisters.

I find it difficult within the limits of a short paragraph to give expression to the deep feeling of gratitude with which the Nursing Sisterhood has inspired all ranks serving in South Africa. The devotion, skill, courage, and endurance displayed equally by the Army Nursing Service and by kindred organisations from the colonies have excited my admiration and fully justified the opinion I have held for years as to the necessity and economy to the service of an ample nursing service for our army. *Some of the nurses who have been the most helpful* have been lent to the Army Nursing Reserve by the great hospitals in the United Kingdom.

I propose in a later despatch to bring to your notice the names of some of the most deserving.

The names of the following officers are also brought to notice for meritorious services:—

ROYAL ARMY MEDICAL CORPS.

[illegible] Major C. A. Munn, Major [illegible] O'Donnell, Major H. J. [illegible] Major M. W. Russell, [illegible] Major A. A. Sutton, [illegible] Major G. E. Twiss, [illegible] Captain T. B. Beach, [illegible] Captain C. W. R. [illegible] W. Hooper, Captain E. M. Morphew, Captain F. J. W. Porter, Captain F. W. Begbie, Captain A. F. Tyrrell, Lieutenant H. Ensor, Lieutenant R. S H. Fuhr, Lieutenant E. T. Inkson, Lieutenant W. H. S Nickerson, Lieutenant C. J. O'Gorman, Lieutenant [illegible] (Roberts's Light Horse), [illegible] Mounted Rifles), Dr. A. H Hopkins (Cape Colony), and Civil Surgeon A. E. Ross.

THE RESULTS OF SANITATION IN THE AUSTRO-HUNGARIAN NAVY.

The good effects of paying attention to sanitary matters are well brought out by Dr. Okuniewski of the Austro-Hungarian Navy in a statistical report on the health of that service which he has compiled for the years 1898–99. A quarter of a century ago the admissions to hospital from the fleet, ashore and afloat, were equal to 1641 per 1000 of strength, but ever since then the numbers have been steadily going down. During the last decade the sick-rate fell to 643 per 1000, while for the biennium 1898–99 it was only 547 and 467 per annum respectively. The great amelioration thus indicated is due to a notable diminution in most of the preventable diseases. At Pola, for example, which formerly used to be called "the home of fever," the admissions on account of malarial affections have fallen to about 30 per 1000 from upwards of 800, the improvement being partly owing to quinine prophylaxis, but in the main to drainage and other sanitary works. But notwithstanding the gratifying evidence of progress thus afforded there still remains room for sanitary improvement at Austria's chief naval station. Typhoid fever continues to commit sporadic ravages every year amidst the population, civil and militant alike, while periodically the disease is said to attain to the dimensions of an epidemic. In order to combat this unfortunate condition of things several new regulations have been issued having reference to the water-supply and its distribution, the markets, and the disposal of sewage, and it is hoped that their execution will prove effectual in controlling the infection. Amongst the diseases which some years since used to swell the naval sick-list to an inordinate extent but which have now almost completely vanished trachoma, scurvy, and small-pox were the most widespread. In 1879 the first-named affection was responsible for 39 admissions yearly per 1000 of strength, and whole ship's companies used to be placed *hors de combat* by the other two. During the last 10 years, however, scurvy may be said to have entirely disappeared from the naval service, although still prevalent to a considerable extent in the army, while, thanks to a rigorous supervision of vaccination, the sick-rate from small-pox has fallen to 0·2 per 1000. Tuberculosis is far less common now than formerly but it still gives rise to three admissions per 1000 and is likewise blamable for much of the loss by death and invaliding. This continuance of an avoidable disease is regrettable, but the sanitary officials are fully alive to the importance of preventive measures, including a stricter examination of recruits, and in all probability the next few years will see a progressive lessening of all the rates. The disability in the navy from venereal disease has diminished during the last 20 years from 104 to 90 per 1000 of strength, the improvement being ascribed to the infrequency of relapses which has attended on a better system of treatment. In the Austrian army the venereal admission ratio is only 60 per 1000 of strength, and, according to Dr. Okuniewski, a similar disproportion in the incidence of the disorder is observable in the naval and military forces of Germany, England, and Italy. The bacterial laboratory at the Pola Naval Hospital has been the scene of two very interesting discoveries. In the first place it was proved that typhoid bacilli conserve their activity and virulence for a period of 20 days in oysters; and, secondly, the important fact was established that the fermented juice of the grape is very highly inimical to the same noxious microbes. Wine infected with typhoid bacilli was invariably found to be sterile after 24 hours. In concluding his interesting report Dr. Okuniewski draws attention to the excellent results obtained at the dental institution which was recently opened at Pola for the benefit of the navy.

TRANSPORT IN WAR.

We have so frequently called attention to the extreme importance of adequate transport in war that the subject must have become wearisome to our readers. One of the greatest difficulties with which the army and the medical service had to contend in South Africa arose from the deficiency of transport, as anyone may perceive who will read what Lord Roberts has said on the subject in his separate report, which has just been published, on the field transport in South Africa. Nor is the British army the only one that has to encounter the transport difficulty and manifest its shortcomings in this respect. The transport arrangements of the German army have, as we now know by a telegram from Peking, broken down under the test of field service in China, where the fighting has not been severe, and a committee has been appointed by Count von Waldersee to inquire into and report upon the causes. The army organisation of the Germans has been always held up as model. This might probably prove to be the case in a big continental war, but it is quite a different matter where the war is at a great distance in the far East and where the land transport arrangements are partly dependent upon what can be conveyed by shipping from Germany, but chiefly upon what can be obtained in the country which is the seat of war.

LORD ROBERTS'S DESPATCHES.

The commendatory despatches of the late Commander-in-Chief at the seat of war in South Africa which have just appeared in the *London Gazette*, will very naturally be read with great interest by all concerned. The Field Marshal passes in review all the leading officers of the campaign whose names are more or less familiar to the public and gives his estimate of the services which they have rendered, as well as his opinion of the work done by the various branches of the service. Our readers will see for themselves what Lord Roberts, in a somewhat lengthy notice, has to say about the Army Medical Service, the civilian and colonial surgeons, the hospitals, hospital ships, and the nursing element. It will be seen that while Lord Roberts highly commends the Army Medical Service as a whole, and alludes especially to the bravery and devotion displayed by so many of the officers of the Royal Army Medical Corps, his praise is to some extent qualified.

THE FRENCH "RED CROSS" IN CHINA.

The French Red Cross Society has rendered important services to the troops of its own nationality engaged in China. Last August a hospital ship named *Notre Dame du Salut* was despatched into Eastern waters, having on board in addition to its own establishment sufficient *personnel* and equipment for two stationary hospitals on shore, and according to a recent account one of these, for 180 patients, has been opened at Nagasaki. The *Notre Dame du Salut* then proceeded to Taku where it afforded aid to a number of sick and wounded French soldiers and sailors, 253 of whom it subsequently brought back to France. Altogether the number of patients treated at Nagasaki as well as on board the Red Cross hospital ship was 656, but full particulars have not yet come to hand. Two hospital ships belonging to the Japanese Red Cross Society, and named respectively *Hakuai-Maru* and *Rosai-Maru*, have also been doing good work in the Gulf of Pechili.

MILITARY AND NAVAL COOKS.

Lord Roberts has given his special sanction to the troops in London to take part in the Army Cookery Contests at the forthcoming Universal Cookery and Food Exhibition which will be held at Knightsbridge from June 11th to 15th. The troops who will be in the London district at that time and who will consequently take part in the competitions will be the Grenadier, Scots, and Coldstream Guards, and (for the first time) the Irish Guards, and also the Wiltshire Regiment. Sailors undergoing training, or who have been taught at the Nautical Cookery Schools of London, Liverpool, North Shields, and Glasgow, will take part in special naval and mercantile marine cookery competitions. The Mercantile Marine will also be represented by boys from various training ships. This section will be under the direction of Alderman J. F. Spence, J.P., of Tynemouth.

"Audi alteram partem."

"THE TEACHING OF ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—In my letter in THE LANCET of Jan. 19th, p. 212, I expressed regret that Lieutenant-Colonel Lawrie had, under the guise of supporting a movement in favour of the recognition of anæsthetics as a necessary part of the medical curriculum, again opened up the chloroform controversy. I contended that the time had not yet arrived for the discussion of what should be and what should not be taught; and Lieutenant-Colonel Lawrie admits, in his letter in THE LANCET of April 6th, p. 1041, the force of this contention. It will be time enough, when the examining bodies have made some system of instruction compulsory, to inquire into, and possibly extend, the present plan of teaching. But although Lieutenant-Colonel Lawrie fully realises this he cannot resist the temptation of continuing his laudable task of collecting and replacing the numerous fragments of the Hyderabad idol. I can only again express my regret that he should persistently obtrude this mending process upon a weary audience. Were there any real worth in his suggestions one might excuse their prematurity; but I fail to find any such worth. I would even go further than this and assert that the suggestions made by him are positively dangerous, and it is for this reason alone that I propose to criticise at some length the position which Lieutenant-Colonel Lawrie has taken up.

In the first place, Sirs, let me remind your readers that a very important change in what may be termed the standard of anæsthesia has almost imperceptibly come about within the past quarter of a century. To put this change in plain words, I may say that the surgeon of to-day—at all events the surgeon of to-day practising in England—not only requires that his patient shall be rendered rapidly unconscious without inconvenient excitement, but that he shall be kept throughout, even for minor operations, in a state of complete muscular relaxation and immobility. Such are the demands of modern surgery—at all events in this country—and it is the duty of instructors in anæsthetics at our hospitals to send out into practice men who will be able to meet the requirements of the modern surgeon. It is not to be wondered at that this change in the standard of anæsthesia has taken place, for even in comparatively minor operations the surgeon who is particular about his results very naturally requires more at the hands of his anæsthetist than the surgeon who practised when only crude methods of anæsthetisation were known to the profession. The value of the assistance given by skilful anæsthetists in such operations as those of abdominal surgery is fortunately becoming more and more widely recognised. The modern anæsthetist has, in fact, to meet demands created by others. Now this means that the anæsthetic which should be employed by the average medical man must be one which can be given in such a way as to eliminate excitement and to such a profound degree of narcosis that no inconvenient reflex phenomena occur. Chloroform is therefore not suitable, whilst ether fulfils nearly every requirement.

I am amused at Lieutenant-Colonel Lawrie's statements as to the London teaching. He affirms that "in London there is no practical teaching in anæsthetics worthy of the name." Now not only is this statement utterly erroneous (as the letters of Dr. Dudley Buxton and Mr. H. Bellamy Gardner in THE LANCET of April 13th, pp. 1104 and 1105, show), but the author of it asks us in the same breath to revert to modes of anæsthetisation which were in vogue in our student days and which have long since been replaced, thanks to the work of Clover, by more suitable methods. Let us examine the advice so magnanimously proffered to the English anæsthetists. Let us submit this advice to some of our leading surgeons. In one of our journals[1] a few years ago Lieutenant-Colonel Lawrie, speaking of his Hyderabad system of anæsthetisation, made the following remarks:—

> The old prejudice against beginning an operation before the patient is "over" was finally cast aside in 1895, and since then nearly all minor operations have been performed under partial anæsthesia with chloroform ...... it is now established as a routine method of practice. ...... The only drawback to it is that reflex struggling may be set up occasionally on the infliction of the wound, but this is merely a temporary inconvenience which can be removed if necessary by pushing the chloroform until struggling ceases or until anæsthesia is complete.

In a work recently published by Lieutenant-Colonel Lawrie[2] the following significant statement appears:—

> Two or three assistants should always be present when chloroform is given, because in a certain percentage of cases it produces excitement and intoxication and the patient may struggle so violently as to become unmanageable if assistance is not at hand.

Perhaps the cheapness of labour in India may render it possible for a retinue of assistants to accompany every medical practitioner when called upon to administer an anæsthetic; but it is fortunately unnecessary for us in this country to adopt such stringent precautions as Lieutenant-Colonel Lawrie suggests.

Again, let us listen to the directions for anæsthetising young children.[3]

> The way to make a young child breathe regularly is to make it cry by holding the chloroform cap close down over its mouth and nose until it becomes unconscious and quiet.

It is, I think, unnecessary to further criticise the above doctrines; they speak for themselves.

In the next place a few words as to the statistics which I quoted. They were not intended to throw into relief the merits of this or that method of administering any given anæsthetic. But even when ingeniously rearranged in tabular form by Lieutenant-Colonel Lawrie they certainly show all that they were intended to show—viz., the lethal influence of chloroform as compared to other anæsthetics in dental surgery. They were compiled on the assumption, which I still hold to be permissible, that in a given period, say of 15 years, the dental anæsthetic death-rate per 1,000,000 would be about the same in Scotland as in London, provided the same anæsthetic were used; whereas if in Scotland chloroform were, as is the case, the routine anæsthetic, and if in London nitrous oxide and ether were, as is the case, the routine anæsthetics, then any marked differences in death-rates might be fairly ascribed to the influences exerted by the anæsthetics themselves. The appalling influence of chloroform as an anæsthetic in dental surgery is thus clearly illustrated, for there were in the 15 years no fewer than 14 deaths in Scotland (12 of them taking place in association with chloroform), whilst in a corresponding period of time there were only two deaths (both under nitrous oxide) in London; and this direct comparison is fortunately rendered possible by the fact that the population of Scotland was, according to the census returns (average between 1881 and 1891) almost equal to that of London.

With figures such as these it is, to my mind, almost incomprehensible that Lieutenant-Colonel Lawrie should still insist on the safety of chloroform in dental surgery. His contention is that by a combination of Syme's principles, certain Eastern developments of those principles, the presence of two or three assistants, and the establishment of partial anæsthesia the risks of this anæsthetic almost or completely cease to exist. But, as I have shown, the so-called Hyderabad methods, even if there were any real merit in them, would be utterly impracticable in this country. Our requirements are of a totally different order to those which apparently exist in India; and we therefore find it necessary to employ anæsthetics and methods which will meet our needs. Lieutenant-Colonel Lawrie's attitude forcibly reminds me of that which might be adopted by a swimming-master, surrounded by a crowd of admiring pupils each of whom has learnt under the able guidance of his instructor to swim across a shallow river with one foot touching the bottom and assistance within easy call. It is quite clear that a long and unbroken record of successful passages from shore to shore might, under such circumstances as these, be chronicled; but what should we think of such statistics? I must leave the profession to answer this question.

All that Lieutenant-Colonel Lawrie's contributions to the clinical study of chloroform demonstrate is that when given to a partial degree and with a due regard to respiration this drug is safer than it otherwise would be. But is it necessary to beat the big drum to announce this fact? That the chloroform death-rate may be reduced by working upon such lines almost goes without saying, but his crude plans of procedure would certainly not be tolerated in the practice of any leading English surgeon. Some years ago Lieutenant-Colonel Lawrie came with two assistants to the London Hospital and chloroform was administered in the Hyderabad fashion in two straightforward cases. But the type of anæsthesia produced was distinctly inferior to that which may be witnessed any day of the week in the operating theatres of our hospitals. A case presenting greater scope for skill in anæsthetising was prepared for Lieutenant-Colonel Lawrie at University College Hospital, but although the theatre was crowded in expectation of his arrival he failed to put in an appearance.

In summing up this matter I fail to see what there is to be learnt from Lieutenant-Colonel Lawrie's writings. When one realises the simplicity and crudeness of his methods one can readily understand his statement that he finds "a month of clinical teaching more than sufficient to render the average student capable of administering chloroform"; nor, considering the type of his "anæsthesia," is it surprising that he leaves the anæsthetising "to students and nurses of no special endowments."

Interesting as this correspondence has been, I fear I must decline to continue it further, for I cannot conceive that any useful purpose can be served by discussing such inconvenient and obsolete means of anæsthetisation as those advocated by Lieutenant-Colonel Lawrie.

I am, Sirs, yours faithfully,
FREDERIC W. HEWITT.

Queen Anne street, W., April 13th, 1901.

"THE ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a leading article in THE LANCET of April 6th, p. 1025, with reference to the affairs of the Royal Orthopædic Hospital, which is obviously based upon a letter signed "Hospital Governor" printed in THE LANCET of March 23rd, p. 893.

---

[1] Brit. Med. Jour., July 31st, 1897.
[2] Chloroform, 1901, p. 47.
[3] Op. cit., p. 52.

You have been misled by "Hospital Governor." He is an untruthful person who makes false charges anonymously which he probably will not care to repeat over his own signature. I have never stated that "the value of the hospital site is 30 years' purchase at £1500, or a sum of £45,000." I have never stated (as reported in your leading article) that I obtained my majority by votes specially created "for the purpose of resisting the scheme of selling the site of the hospital."

The opinion of THE LANCET on all hospital matters is of unquestionable value provided that it is based upon accurate information. Such information may be had for the asking if you desire it, and from persons who will be prepared to supply it over their own names. The information of "House Governor" is not accurate and has not been sent to you in the interest of the hospital.

I am, Sirs, yours faithfully,

April 11th, 1901. H. H. MARKS.

⁂ We desire information strongly. We wish to know why the present site of this hospital is being sold.—ED. L.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 23rd, p. 578, I stated that temperance legislation had been tried on a very wide scale in the civilised world, and challenged temperance reformers to mention a single instance of successful legislation under conditions half as onerous as the least onerous that prevail in England—namely, in Westmorland, where the population is 84 to the square mile. In THE LANCET of April 6th, p. 1040, I referred to that challenge, and stated that I had received no reply and that I anticipated none. I was wrong. Dr. T. S. Clouston has accepted the challenge. He instances Norway. But in Norway the density of the population is only 17 per square mile.[1] In other words, the density of population in Norway is not half but nearly five times less than in Westmorland. Dr. Clouston, therefore, has not observed the conditions of the challenge. Nevertheless, I am willing to waive the point. He states that owing to legislative interference the consumption of spirits has fallen from 16 litres per head to 3 3 in Norway. He omits to mention that the consumption of beer[2] and laddevin[3] has risen enormously. In 1897 in Christiania, the capital of Dr. Clouston's "sober" land, the arrests for drunkenness were 94 per 1000 of the population.[4] In London they were 7 35.[5] In New York 13 in the year 1898.[6] In Chicago 23.[7] In Portland, the capital of the classic prohibition State of Maine, 42.[8] In Boston, which is not a prohibition city, 45.[9] But Boston is surrounded by a prohibition area, whence nearly half its inebriates are derived.[10]

Drunkenness has greatly increased in Norway of late years. Thus in Bergen, the second largest town, the arrests for drunkenness per 1000 of the inhabitants were 12·1 in 1892. In 1899 they were 25 9.[11] The Scandinavian method of temperance reform took origin in Gothenburg, whence its name. In 1895 the arrests for drunkenness in that city were 33 per 1000. In 1899 they were 58 per 1000.[12] The increasing drunkenness of Gothenburg is admitted on all hands except by the inn-keepers and brewers who are interested in the sale of beer.[13] Dr. Clouston's reference to Norway is evidently not happy. Judged by the police returns its inhabitants are drunken to an extraordinary degree. He may, of course, argue that, since conditions vary police returns are fallacious. But consider the case of Portland, where only the drunken *and* disorderly or incapable are now arrested, the merely drunken being too many for police control.[14] Dr. Clouston has appealed to Messrs. Rowntree and Sherwell and I have restricted my reply to their pages. They are "temperance reformers," but, on the whole, their book is the most telling indictment of "temperance reform" that ever yet was penned.

Dr. Clouston would permit moderate drinking, but would suppress drunkenness. His aim is laudable, but unfortunately all attempts to attain it have resulted hitherto only in the suppression of the moderate drinker. The *per capita* consumption of alcohol is easily lowered by the imposition of repressive legislation, but the actual amount of drunkenness generally rises *pari passu.* A more extended study of Messrs. Rowntree and Sherwell's book will afford your correspondent plenty of evidence of this curious and significant fact. The *per capita* consumption of alcohol is very high in the wine countries where the amount of drunkenness is least.[15]

Dr. Clouston states that 99 per cent. of my professional brethren believe that parental drinking is a cause of filial degeneration. I dare say he is right. For years I have protested against the prevailing medical neglect of modern teachings of heredity. Will any member of his great majority supply evidence that parental drinking *does* beget filial degeneration? I personally am prepared to supply conclusive evidence that it does not. I fear I have already exceeded the limits of your space, but there are one or two of Dr. Clouston's remarks that I ought not to leave unnoticed. He says pretty plainly that I advocate the spread of disease and drunkenness. Will he be good enough to supply chapter and verse? He says that I incur a great responsibility and that I ought to be very sure of my ground. I fully recognise the responsibility, but I happen to be very sure. The history of "temperance reform" on the lines advocated by Dr. Clouston embraces almost the whole world, and extends over thousands of years. It is one long record of disastrous and demoralising failure—of failure which has grown more and more immediate and complete with the increasing density of the world's population and the increasing complexity of the world's civilisation. My responsibility is shared by others—by those who continue to advocate methods of temperance reform which were proved impracticable a thousand years ago.

I am, Sirs, yours faithfully,

Southsea, April 14th, 1901. G. ARCHDALL REID.

To the Editors of THE LANCET.

SIRS,—Dr. T. S. Clouston's contributions in THE LANCET of April 6th (p. 1039) and 13th (p. 1103) are in many ways welcome. As pointed out in your leading article of March 23rd (p. 873) your correspondent has made some useful observations recently on the alcohol question and is entitled to a respectful hearing, and he now enters the lists in response to your comparison of him to Sir John Simon and Snow. Permit me, Sirs, to confine my remarks chiefly to an examination of his first letter, the second being a direct challenge to Dr. Archdall Reid himself. Dr. Clouston's opening contention that the alcohol question can and must be solved "through the application of scientific facts and principles" is the fundamental doctrine of the Reid school, which it is a pleasure to find him enunciating for himself. But it is disappointing to find that his scientific facts are entirely elementary. The fact that alcohol is injurious was known to the world thousands of years before physiology became a science and the microscope was invented. Kraepelin's experiments and the details of pathological morphology which constitute Dr. Clouston's scientific facts are interesting as confirming common knowledge, but the public will have nothing but contempt for us as a profession if we now propose action on the ground of these undisputed observations years after a more liberal-minded laity have begun action, if imperfectly, on the ground of common observation and experience. But if it is impossible to discover in Dr. Clouston's letters any other facts which may be called scientific it is easy to point out much argument which has no foundation in science. It is not possible to deal with all of this in the limits of a letter, but one or two points cannot be passed over.

In his first letter (April 6th) we find Dr. Clouston brushing airily aside the only attempt that has been made to deal scientifically with the temperance problem. Dr. Reid's work upon the alcohol question, which includes a scientific study of every aspect of the subject and an indication of a possible road to a permanent solution at last, is thrust away without discussion in the company of transcendental theories of heredity which have nothing to do with the subject, by one who professes to take his stand upon scientific grounds. Dr. Reid's edifice, built upon a solid scientific base, is to be ignored while Dr. Clouston raises flags in exultation over half a dozen loose bricks. *But your correspondent is not content to magnify* the importance of a few physiological experiments and microscopic pathological facts and to proclaim Dr. Reid's work to be of no importance; he goes on to use the vague stock utterances of those to whom nobody looks for scientific enlightenment. What ground has he for the assertion that "adverse hereditary influences" and "toxic interference with the germ plasm," &c., "*make for national decay*"? *How* does he propose to prove that drunkards "hand down a progeny with all their own tendencies accentuated"? If he possesses evidence to prove these statements then, Sirs, once more let us beg that it may be forthcoming. But if, like "M.D., B.S. Lond.," and Mr. A. Marsden, your correspondent shrinks from being hailed the first great discoverer of this century—the discoverer of a transmitted acquired character—I trust that at least he will examine the contentions of Dr. Reid more closely.

---

[2] Op. cit., p. 476.

[3] Op. cit., p. 475.

[4] Op. cit., p. 487.

[5] Op. cit., p. 677.

[6] Op. cit.

[7] Op. cit.

[8] Op. cit.

[9] Op. cit., p. 158.

[10] Op. cit., p. 318.

[11] Op. cit., p. 483.

[12] Op. cit., p. 461.

[13] Op. cit., p. 463.

[14] Op. cit., pp. 159, 160

[15] Op. cit., p. 613.

Dr. Clouston's second letter, curiously enough, is directly concerned with the doctrines he declares *to be of no account*, but he has exercised his mind during a week only to *collect opinions similar to his own that the acquired effects* of disease and alcohol are transmissible. It ought to be unnecessary to remind Dr. Clouston that preconceived opinions do not alter facts and often must vanish before a scientific exposition of facts; he will find confirmation of this truism in the history of Darwinism and of Listerism and of every epoch-making theory, and also, alas, precedents for his own remarkable attitude. Even in recent times the *opinions* of the medical profession have, despite opposition such as your correspondent now offers, undergone transformation—*e.g.*, regarding the transmissibility of tuberculosis and even regarding the value of alcohol in the treatment of disease. *His* appeal to authority is of no scientific value—nay, it is of no controversial value—in face of the fact that Dr. Reid's views have lived already for over five years and that not one of his arguments has been proved *fallacious* by his crowd of assailants. If Dr. Clouston had read "The Present Evolution of Man" he would *not* have found it necessary to inquire for Dr. Reid's proofs that neither disease nor drink affects the offspring; he will find them in that book founded on Darwinism, on Evolution, which he will remember Huxley pronounced to be no longer a speculation but an historical fact. A study of them will place him in a position to bring forward any conflicting evidence which he may possess or will compel him to go through the painful process of revising his convictions.

The last point to which I must refer is contained in the following sentence: "Another thing the medical profession *is specially fitted* to do, and that is to judge rightly the safe limits of the pleasures and the social and personal amenities which alcohol in physiological quantities may secure, and *to* pick out the persons who can safely indulge in such pleasures." This I take to be a grave statement that Kraepelin's experiments or some other researches which are not specified have conferred on the profession the power to measure with precision the personal equation in regard to alcohol. But we are *left to wonder* how the power is cultivated, whether it is anything more than that possessed by every good judge of character, and how the statement quoted is to be reconciled with the equally emphatic one of those who maintain on the ground of experiment that alcohol is injurious to all men, even when taken in moderation. Why does not Dr. Clouston in the courage of this *conviction propose amongst his* legal *provisions an examination* of every individual at the right age by a board of experts in order to determine this personal equation and issue certificates permitting the proper amount of pleasures and amenities? Perhaps Mr. W. S Gilbert may be induced to supply the omission. It is scarcely necessary to examine in detail the proposals for legal provisions with which Dr. Clouston's first contribution closes. He is no doubt aware, even if he has perused Messrs. Rowntree and Sherwell's admirable work only in a cursory manner, that practically all of his proposals have been tried on a large scale in America, New Zealand, Scandinavia, and elsewhere and have failed dismally; but he advances no reasons why such measures, even when rechristened "scientific," should be successful at home.

Allow me, Sirs, with all deference, to suggest to your correspondent that it is unfair as well as unscientific first to proclaim as of no account, then to condemn on no evidence, and lastly to misrepresent views with which he is not in accord. Whatever may be the characteristics of "the *pursuit of a fatalistic inertia*" nothing can be further from the truth than to suppose that the Reid doctrine implies in *regard to alcohol* that natural selection must be left to take its course, or to suppose that there is any desire to "put a *spoke* in the wheel of health reform and social amelioration." Dr. Clouston *evidently* is *unacquainted* with Dr. Reid's *remedy* just as he is with his facts. The Reid school takes its stand on science, is zealous for the race as well as for the individual, and believes that they may be benefited *together* once the true (and at first sight not obvious) scientific facts are recognised more generally.

I am, Sirs, yours faithfully,
H. LAING GORDON.

Honor Oak road, S E, April 15th, 1901.

To the Editors of THE LANCET.

SIRS,—After Dr. T. S. Clouston's able defence in THE LANCET of April 13th, p. 1103, of the position taken up by me in my letter of March 23rd, p. 892, I need scarcely trouble you with any further remarks in reply to Dr. Reid's onslaught. After reading Dr. Reid's letter I could *only conclude* that he *knew* nothing of the homes of the drunken poor and the lives that their wretched offspring have to *live* and that the lessons of all past sanitary and social reforms have been lost upon him. We have heard of the "ocean and the broom" before, but will *Dr.* Reid *please* tell me if the chances of two young pretty girls growing up into healthy, respectable mothers are the *same*, when you place one behind a bar and the other in, say, his own house, to look after his children? There *seems to* be a difference of point of view in the case of Dr. Reid (and other members of the Society for the Study of *Inebriety*) and that of social reformers. I agree with Dr. Reid *that* if *you surround* a drunkard with public-houses and give him his freedom no legislation will make him sober, but I still maintain that society has the power to limit the creation of drunkards. I am, Sirs, yours faithfully,

April 16th. M.D., B S. Lond.

CONTINUOUS ADMISSION OF AIR DURING ETHER ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—Some months ago I pointed out in THE LANCET the ease with which chloroform could be administered from a Clover's ether inhaler when the bag had been *removed*. *Modifying* the *same* idea to the administration of ether, I find that, after inducing full anæsthesia with nitrous oxide followed by ether, it is possible in many patients to *maintain the* anæsthesia with the bag *removed and the* indicator turned nearly or quite on to full. By *so* doing the patient gets a supply of fresh air mixed with the ether at each inspiration, instead of *one* or more inspirations of air at intervals when the face-piece is raised, the patient between these intervals breathing in and out of the bag. *The supply of air is thus* made *continuous* instead of intermittent. The result is that the asphyxiation symptoms of ether anæsthesia are largely avoided, the breathing being comparatively quiet and the face pink instead of cyanosed, these differences being very marked. The method involves the use of a larger amount of ether than when using the bag, but this is more than compensated for by the improved type of anæsthesia.

I am, Sirs, yours faithfully,
C. HAMILTON WHITEFORD,
Senior Anæsthetist, South Devon and East Cornwall Hospital.
Plymouth, April 12th, 1901.

MAJOR-GENERAL BADEN-POWELL'S DESPATCH *re* MAFEKING.

To the Editors of THE LANCET.

SIRS,—The following appears in Major-General Baden-Powell's despatch: "Victoria Hospital (Base Hospital), 70 beds: Major Anderson, R.A.M.C., principal medical officer: Dr. W. Hayes (*acted as P.M.O. during the first part of the siege*), &c., &c." Further on again: "On outbreak of war," the General writes, "I took over the Town Hospital [Victoria Hospital], but at first the administration was *not* satisfactory, on account of the want of supervision over expenses of stores and sanitation. I therefore appointed an issuer and store-keeper and a sanitary inspector, &c., &c." The orders of the day published at Mafeking on Oct. 10th, 1899, contains the following: "*Defences:* W. A. Hayes, Esq., M.R.C.S. Eng., L.R.C.P. Lond., is placed in charge of all medical and ambulance arrangements in connexion with the defences of the town of Mafeking." The orders of the day dated April 30th, 1900, contain the following: "*Appointments:* Owing to the illness of Dr. W. Hayes, Major Anderson, principal medical officer of the Defence Forces [the Protectorate Regiment], will take over charge of the Victoria Hospital with effect from the 27th inst." On April 27th I got severe blood-poisoning and was confined to bed—*that is, 20 days before the siege ended.* From the despatch quoted it would appear that Major Anderson, R.A.M.C., acted as principal medical officer during the greater part of the siege; as a matter of fact, he only acted as such for 20 days.

I am, Sirs, yours faithfully,
W. A. HAYES.

Mafeking, March 21st, 1901.

AUTHORS' AGREEMENTS.

To the Editors of THE LANCET.

SIRS,—The reviewer of the current "Literary Yearbook" in THE LANCET of April 6th, p. 1020, has a right to his opinion that my article on the above subject is "ill-informed"; but you will allow me, I feel sure, to correct him as to a matter of fact. He does me a grave injustice in calling attention to what he considers a damaging omission, where I neglect to mention "the royalty which an author might fairly expect to receive under the royalty system." Need I say that the omission is intentional; that the avowed intention of the article is to consider *forms of agreement* in general—not any particular instance; and that, finally, if I were required to give the "royalty which an author might fairly expect to receive under the royalty system," it would be first necessary for him to submit to me data governing a particular case before I could do so—i.e., "an author's" name, his manuscript, and the name of the publisher considering it. In trade there is no such thing as a fixed, abstract, or "ideal price" for anything irrespective of its market.

May I add that your reviewer has perhaps written in ignorance of the fact that no less than 13 pages of the latter part of this work are devoted to "tables of royalties," from which any person of average intelligence might, without distressing it, have inferred: (1) that an average royalty is 10 per cent., since it comes exactly mid-way between the two extremes—2½ and 20 per cent.; and (2) that, postulating a certain sale for a book at a certain price, an author is at once placed in a position to decide from the results shown on these tables whether a royalty offered him by a publisher affords a fair return for his labour.

I am, Sirs, yours faithfully,
Burleigh-mansions, W.C., April 12th, 1901. CHARLES WEEKES.

⁂ Our reviewer, to whom we have submitted Mr. Weekes's letter, replies as follows: "I had no doubt that the omission of all indication as to what royalties should be expected by an author was intentional. But by the omission the whole section of the article dealing with royalties is rendered useless to authors who are surely concerned in the contents of a literary year-book. The publication of books in general was not apparently being discussed by Mr. Weekes under the royalty system, but only that of fiction (see page 28), a limitation which I pointed out before criticising the article. It should have been perfectly easy for Mr. Weekes to indicate what sort of novel by what sort of author would carry a royalty of 25 per cent., and what writers must put up with 10 per cent., the royalty that he now tells us is an "average" one, whatever that may mean. I knew that the book contained tables of royalties, though Mr. Weekes makes no reference to them in his article. The tables are arithmetical guides, quite useful, but in no way supplying the deficiency in Mr. Weekes's article—a deficiency which, to my mind, stultifies his editor's prefatory promise of impartiality."—ED. L.

SUCCESSFUL OPERATION IN FULMINATING APPENDICITIS.

To the Editors of THE LANCET.

SIRS,—In the report in THE LANCET of April 13th, p. 1083, of a case of appendicitis related by me at the last meeting of the Kidderminster Medical Society it should have been stated that the consultation was held and the operation was performed on the Monday when acute diffuse peritonitis had occurred. Had it been a case of "localised peritonitis," as appears in your report the patient's recovery would not have been remarkable, but the mortality after operation in these fulminating cases is so appalling that successful cases are worthy of record.

I am, Sirs, yours faithfully,
J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.

Kidderminster, April 14th, 1901.

"GNATS AND MOSQUITOES."

To the Editors of THE LANCET.

SIRS,—My recently published "Handbook" on this subject is out of print, and my publisher has telegraphed to me in India that a reprint, to supply an urgent demand, is necessary. Our knowledge of the life-history and habits of the malaria-carrying species is, however, growing so rapidly that a mere reprint appears to me out of the question—at any rate as regards the first or general part of the work. Will you kindly permit me to state through your columns that a new issue brought as far as may be up to date will be ready in May? I am, Sirs, yours faithfully,
G. M. GILES,
Lieutenant-Colonel, I.M.S.

"POST-PARTUM HÆMORRHAGE."

To the Editors of THE LANCET.

SIRS,—I have been much interested in the graphic paper by Mr. E. Stanmore Bishop on Post-partum Hæmorrhage in THE LANCET of April 13th, p. 1069. Having had an extensive midwifery practice in the past amongst the "well-to-do" I have had what I presume would be considered a fair average number of these bleeders, and I recall my terrible anxiety as to the result even now with a shudder which he so vividly depicts in his paper. These cases would come on regularly time after time in the same people. The labour would be quite an ordinary one, the placenta and membranes coming away without exertion or hurry, the uterus contracted, abdominal bandage put on, and everything seeming right. In 20 minutes' time the uterus would relax and the most alarming hæmorrhage come on. This has been the history of a large number of these bleeders in my experience. It is not necessary for my object to narrate the different methods employed; but though I never had a death from post-partum hæmorrhage it is a marvel to me that none succumbed. When engaged to attend these ladies in a subsequent confinement I knew what would happen and I went in dread—ergot in full doses, hot-water intra-uterine injection, &c., notwithstanding. At last one day, when everything seemed to fail, in desperation I plugged the vagina well up to the cervix, at the same time holding the uterus firmly down into the pelvis. Then having the patient on her back, I fixed a large firm cushion pad, book or pin-cushion, just above the uterus and bound it so firmly by bandage that it was impossible for the uterus to expand. In most cases except in very fat persons this is very easily accomplished. There was no more hæmorrhage. In six hours' time the plugs were removed and the uterus was thoroughly syringed out with lukewarm water till not a trace of clot was visible. No further hæmorrhage resulted in any of these cases. This practice, I am aware, was very much opposed to the teaching of my day, but the result was so good in my first case that ever after when these bleeders were delivered it became my practice always to plug more deliberately and carefully as soon as the labour was completed and to fix down the uterus as I have described, being very careful not to allow more than six hours to elapse before removing the plug. The clots that were then removed were not large, proving that the uterus could not distend. It always seemed to me that the small soft clot of blood which remained stimulated the contraction of the uterine muscular tissue, and that the early removal of clots and plugs prevented the coming on of any septicæmic conditions. Certainly all hæmorrhage was stopped at once by this procedure. Having found such confidence and comfort from this in my own practice, and believing that with adequate cleanliness and antiseptic precautions it will be found a safe method of practice in these terrible and most anxious cases, I venture to ask you to publish this letter.

I am, Sirs, yours faithfully,
Z.

April 15th, 1901.

TITLES OF BOOKS PUBLISHED 1898-1900.

To the Editors of THE LANCET.

SIRS,—We are preparing to publish Volume VI. of the "English Catalogue of Books," 1898-1900, which completes the list of works produced during the century. As we wish to make it as complete as possible, may we ask those of your readers who have published books between Jan. 1st, 1898, and Dec. 31st, 1900, for the full titles, sizes, prices, month and year of publication, and author's and publisher's names, to be sent as soon as possible, addressed to Editor, "English Catalogue of Books,"

Care of yours faithfully,
SAMPSON LOW, MARSTON, AND CO, Ltd.
St. Dunstan's House, Fetter-lane, London, April 17th, 1901.

P.S.—Particulars of books which have already appeared in the *Publishers' Circular* or in the annual volumes of the "English Catalogue of Books" are, of course, not required.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Increase of the Plague Epidemic.—Success of the Dufferin Fund in Aid of Medical Relief to Women in India.—The Queen Victoria Memorial Fund in India.—Recovery of Medical Fees: a Novel Procedure.

PLAGUE has caused 11,560 deaths throughout India during the past week. The mortality is increasing with alarming rapidity in the Lower Provinces. Of the above total no fewer than 7315 deaths occurred in the Bengal districts. In Calcutta there were 1040 deaths. The plague cases reported in this city were 1199 against 993 during the previous week and the number of fresh living cases seen was 345 Disinfection continues to be extensively practised, not only in respect of the rooms and houses where the cases occur but in many of the adjoining houses. The process adopted consists in flushing the floors and spraying the walls with the standard solution of perchloride of mercury. Cases continue to occur in the disinfected quarters and it is impossible to show that the measure possesses much value. The outbreak in Calcutta now is more severe than that of last year notwithstanding the repeated disinfections which have been practised. As I have before remarked, however, the authorities are apparently able to account for nearly all the plague deaths and the investigations made after death indicate the exact location of the cases. The reported plague deaths in Calcutta nearly account for the excess mortality, and that is more than can be said for any other city. The disease is spreading in Benares and has reached to the cantonment It continues to progress from village to village in the Gardaspur and Sialkot districts of the Punjab. In Bombay city plague has caused over 1000 deaths during the past week. An examination of the total deaths in this city since the plague appeared in 1896 shows an excess mortality over the average of 120,000. The official reports only give 60,000 deaths from plague since its commencement in September, 1896, so that there is a very large balance to be accounted for. If the system adopted in Calcutta had been applied to Bombay it is most probable that the greater part of this excess would have been found to be due to plague, and it is almost safe to say that Bombay city has lost 100,000 of its inhabitants from plague.

The Dufferin Fund has been a great success, and in the sixteenth report just issued is given an account of the medical relief afforded to women in zenana hospitals and dispensaries. Lady Curzon has actively interested herself in the movement and Lady Northcote has given liberally to the fund. There are hospitals which are wholly maintained by the association and others which are aided by the fund or have been started through its agency, and many of the female officers have been assisted in their studies from the fund. Over 247 hospitals were maintained and over one and a half millions of women and children were afforded medical relief during the past year. The hospitals are distributed all over India and some have been started by the liberality of native princes under the auspices of the association. There are no fewer than 373 medical women in various grades now studying in universities, schools, and classes throughout the country. The central provincial and district branches seem to be in a flourishing financial position, as it is stated that between them they possess invested funds of over 22 lakhs. The central committee in controlling this large organisation only spent Rs. 4850 on its entire office charges, which speaks volumes for the economy with which the funds are expended.

The Queen Victoria All India Memorial Fund now amounts to over 26 lakhs. This is on the basis of a maximum subscription of one lakh, but it will be remembered that several of the native princes offered five, 10, and even 15 lakhs apiece. Afterwards it was thought advisable to limit the maximum subscription as plenty of money was forthcoming. The towns and cities in the provinces contemplate having additional memorials of their own, and Delhi proposes to establish a Victoria Hospital for Women.

March 28th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Birmingham Consultative Institution.

ANOTHER phase in the attitude of the promoters of this scheme has just been displayed. It will be remembered that the present occupant of the post of consultant tendered his resignation some weeks ago, his duties to terminate on May 21st. This was thought by some to be a favourable opportunity for the reconsideration of the position between the profession and the authorities of the institution. No formal move has been made from either side, and nothing has been done beyond general expressions of opinion and a vaguely expressed wish for a friendly discussion. The members of the committee of the profession, at present the same as were originally appointed, have not been approached, though they are quite willing for a conference under proper auspices, such as those of the Lord Mayor of the city. The leading spirit of the movement is still of opinion, he says, that there is a large class between the absolutely poor and the fairly prosperous for whom some provision is required on terms within their means and on conditions which will not offend their self-respect. This pious opinion, therefore, is to constitute the demand which is to regulate the supply, that is, the price at which the consultations are to be fixed—namely, half a guinea each. Again and again it has been pointed out that most of the leading members of the profession are willing to see patients for this amount under certain safeguards as to the genuine position of the patients, any inquiry as to which is repudiated by the powers of the consultative institution. The committee have resolved to continue the institution upon the same lines, and with true commercial instinct as to the power of lucre they have issued advertisements for a consulting physician and a consulting surgeon at a salary of £500 a year each. The holder is to be debarred from general practice, and the requisites in either case are, the advertisement states, a high diploma from one of the Colleges of England, Scotland, or Ireland and hospital and other experience It will be well that any aspirants should view the position carefully and above all that they should consider the honour and interests of their profession as the paramount motives of their lives

Birmingham and Midland Hospital for Women.

The annual meeting of the subscribers of this institution was held on March 21st The report stated that the number of new cases in the out-patient department had been 3323, the total number of new and old cases being 17,744. 427 patients had been admitted to the in patient department—an increase of 23. The total number of operations had been 410—an advance of 26 as compared with last year. The number of cases of abdominal section had been 204, with six deaths The financial statement showed an expenditure of £3045—£208 over the ordinary receipts. It was stated that the enlargement and rebuilding of the hospital were becoming an absolute necessity, and a scheme had been formed for carrying this out. The population of Birmingham and the immediate neighbourhood, it was pointed out, had increased 31 per cent. during the last 20 years, while the number of beds in the hospital had gone down from 22 to 20. Various votes of thanks were passed.

Hospital Saturday Convalescent Homes.

The ninth annual reunion of those who have been patients at the Hospital Saturday Fund Convalescent Homes at Llandudno was held at the Town Hall on April 1st. It was stated that 11,535 patients had, passed through the homes. They were supported entirely by the working men and women of the city after they had presented an annual sum of £10,000 to help to carry on the work of the hospitals in the town. The homes were declared to be unique. They were open first to regular subscribers, but if there were any beds to spare the committee sent down any who were in need of change of air, good food, and rest to restore them to health and strength. An organ recital, a concert by the City Police Band, lime-light views, &c., made up an admirable programme for an evening which was well spent and much enjoyed.

The Housing of the Poor.

It is an acknowledged fact that a large number of the poorest classes live under conditions which are absolutely unhealthy and immoral. Attention has lately been given by philanthropic citizens to the methods best adapted for the relief of those who suffer so much. It is shown that in this city the poor live in self-contained houses, in tenement houses, and in common lodging-houses, and that though much has been done by the Health Committee towards getting insanitary property condemned as unfit for habitation, or properly and adequately cleaned and limewashed, there is still a vast amount to be done. Some legal results are likely to follow the publication of some articles upon this subject reflecting upon the duties and action of the medical officer of health of the city.

April 16th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Sir John T. Brunner and the Eyesight of School-children.

SIR JOHN T. BRUNNER, Bart., M.P., is showing a practical interest in, and sympathy with, school-children suffering from strabismus. He has offered to provide schools with spectacles to alleviate this defect. The offer applies to all elementary schools, board and voluntary alike, in the Northwich parliamentary division.

The City Council and the British Congress on Tuberculosis.

The Corporation of Liverpool have voted 100 guineas towards the expenses of the British Congress on Tuberculosis which is to be held in London in July.

The Annual Report of the Head Constable.

A perusal of the annual report of the head constable reveals a decrease of crime in the city. Crimes of violence (murders, woundings, &c.) numbered only 135, being three less than the very small number in the previous year and exactly one half of the number recorded five years ago. Cases of drunkenness were slightly in excess of last year, the numbers being 4180 as against 4069 in the year 1899. The progressive decrease in cases of drunkenness is shown by the reduction of the number of convictions for that offence since the year 1895, which then reached 5505. Proceedings were taken against 3152 persons for breaches of sanitary laws. There are six fully-equipped police horse ambulances at work, four of which are stationed at the leading hospitals; the services of the ambulances were required 2056 times last year. 1673 constables hold certificates from the St. John Ambulance Association, 1030 of whom have also received medallions. The police rendered first aid in 671 emergencies; splints were applied in 155 cases, bandages in 336 cases, and tourniquets in 11 instances. Artificial respiration was resorted to in 22 cases, whilst emetics were administered 25 times. Other first aid involved 122 cases. 431 constables received special commendation from medical men for valuable first aid. The police were the means of restoring 3060 lost children to their parents. 1636 cases of insufficiently clothed children were inquired into by the police and reported upon to the Liverpool Police-aided Clothing Association. 67 lunatics were taken charge of by the police. The Order of St. John of Jerusalem in England conferred their silver medal for bravery in saving life on land upon one constable. The medal was presented by H.R.H. the Prince of Wales, Grand Prior of the Order, at Marlborough House on July 11th last. The Liverpool Shipwreck and Humane Society have conferred medals on 12 members of the force besides votes of thanks to other constables. The total number of fires attended during the year was 790, as against 882 in the previous year. The authorised strength of the brigade consists of 52 permanent firemen together with 360 auxiliary firemen (police constables), all of whom are trained men and are regularly drilled in the use of fire appliances, &c.

Appointments at the Liverpool Royal Infirmary.

The vacant post of honorary physician to the Liverpool Royal Infirmary has been filled by the appointment of Dr. T. R. Bradshaw, the senior assistant physician. During the last few years Dr. Bradshaw has published original work with regard to the condition to which he had given the name of myelopathic albumosuria, a disease which was quite unknown to the profession until he made known his observations on the subject. A keen contest is anticipated for the vacant post of honorary assistant physician to the Royal Infirmary. There are already nine candidates in the field, all of whom possess qualifications of a high order. Five of the candidates are assistant editors of the Thompson-Yates laboratories reports and have been largely engaged in pathological work.

April 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Vital Statistics.

FROM the statistics for March it appears that the mortality was at the annual rate of 14·5 deaths per 1000 persons in Perth, 16 1 in Leith, 17 9 in Aberdeen, 19·9 in Greenock, 20 0 in Dundee, 20·5 in Paisley, 22·1 in Edinburgh, and 23·2 in Glasgow. Of the total 2968 deaths 1039, or 35 per cent., were of children under five years of age. Miasmatic diseases accounted for 13 3 per cent. of the total deaths. Whooping-cough has the most fatal epidemic influence; it caused no less than 6·0 of the total number of deaths. Small-pox was responsible for 74 deaths; all of these with one exception (in Paisley) occurred in Glasgow. During the previous month the deaths from small-pox numbered 57—in Glasgow 54, in Paisley two, and in Aberdeen one. Measles caused 53 deaths, diphtheria 22, scarlet fever 16, enteric fever 20, typhus fever two, and puerperal fever eight. 13 deaths were registered as due to alcohol, 12 of these being attributed to chronic alcoholism and one to delirium tremens. The deaths certified as due to phthisis pulmonalis numbered 252, or 8 per cent. of the total; other diseases of the respiratory organs (excluding whooping-cough) caused death in 613 instances—a percentage on the total deaths of 20 7 per cent. The deaths from violent causes numbered 96 and included a suicide by cut-throat and one by coal-gas poisoning. Five males and four females were aged 90 years or upwards; one of these, a widow, had reached the age of 99 years.

Glasgow Ophthalmic Institution.

The annual report of this institution, which is now conducted as a branch of the Royal Infirmary, has just been issued. It affords evidence of the increasing usefulness of the institution and would appear to show that advantage has followed union with a larger organisation. The increase in the number of patients compared with the previous year reaches 10 per cent., and the cliniques conducted by Dr. Maitland Ramsay and Dr. J. Rowan have attracted a considerable attendance of students. Indeed, it has been found necessary to extend the class-room accommodation and to make provision for students in attendance on the out-patient department. During the year the electric light has been introduced throughout the whole hospital, to the great advantage both of patients and staff. A Roentgen-ray apparatus and a large electro-magnet have also been supplied, and Dr. John Gilchrist has been appointed electrician in charge of these departments. The operating theatre has been entirely remodelled and fitted up in accordance with the requirements of modern surgery. It is to be known in future as the Overtoun operating theatre in acknowledgment of the fact that its present complete condition is due to the generosity of Lord Overtoun. The ophthalmoscopic room has also found a generous patron who has entirely re-equipped it and who desires to remain anonymous, and the male wards have been re-floored and provided with the most approved pattern of hospital furniture at the expense of Mr. Peter Mackinnon of Ronachan and Mr. Alexander Findlay of Motherwell. The institution has certainly advanced in public and professional confidence in recent years, a result largely due to the medical staff and in some measure also to an improved system of management.

Philosophical Society of Glasgow.

At a meeting of this society on April 10th a paper was read by Dr. H. C. Marr of the Lenzie Asylum on "The Story of the Insane, with Special Reference to Glasgow." Dr. Marr, in the course of his lecture, traced the evolution of the present methods of treating insanity and gave an historical account of the several asylums existing in the neighbourhood of Glasgow, beginning with the town's hospital, founded in 1737. The separate villa system of treatment, as practised at Alt Scherbitz, was also described. In discussing the influence of alcohol as a cause of insanity Dr. Marr remarked that under the Inebriates Act relatively few of the victims of alcoholism were reached, and he urged the adoption of more effective methods to secure the desired end.

Marine Biological Station at Millport.

The authorities in charge of this institution are determined to realise as efficiently as possible the intention of its founder, the late Dr. David Robertson, and to organise a complete scheme of practical and laboratory work for the study of marine biology. On April 10th the committee received representatives from various educational bodies at the station with a view to extend a knowledge of the educational resources at their command. Dr. J. F. Gemmill, the President, gave a sketch of the new teaching arrangements, which include a course of lectures on marine zoology and botany, with practical demonstrations on Saturdays from April 27th to June 15th inclusive, the introductory lecture to be delivered by Sir John Murray, K.C.B., F.R.S. The visitors were afterwards conducted over the laboratories, tank-room, and museum by Dr. James Rankin, and then proceeded on a dredging excursion on the steam-launch *Mermaid*, recently presented to the institution. It is hoped that the new teaching arrangements will encourage the practical study of natural history among board school and other teachers, upwards of 40 of whom have already entered their names for the new classes. The science students in the University of Glasgow also find the station an admirable centre for practical work and the younger dons in the science faculty are energetically assisting in its development.

Small-pox in Glasgow.

The epidemic continues to show a decided decline. The total admissions for the week ending on April 14th numbered 33, and the patients under treatment on that date had fallen to 190. In his weekly report the medical officer submits a tabulated statement showing the proportion of revaccinated persons found in tenements from which small-pox patients were removed to hospital. The figures show that of 2730 persons over five years of age found in infected tenements 1847, or 67 per cent., had been revaccinated prior to invasion. These figures include the whole city. But when particular districts are studied it is found that the proportion of the revaccinated displays wide variations. In 26 tenements in the eastern division it was as high as 83 per cent., whilst in 12 tenements in the northern district it fell to 56 per cent.

University of Aberdeen.

The celebration of "Founders' Day" in connexion with the University was, after a lapse of several generations, revived last week, when there was a series of functions. A dinner, attended by 200 distinguished graduates, took place in Aberdeen Joint Town and County Hall on April 8th, the Very Rev. Principal Marshall Lang, D.D., presiding. A special commemoration service was held in King's College Chapel on the following morning and in the afternoon the graduation ceremony came off in the Mitchell Hall, Marischal College. Five students received the degrees of M.B., C.M. (old regulations), and 23 those of M.B., Ch.B. (new regulations). Six practitioners had the degree of M.D. conferred upon them after examination; and among others Dr. Angus Fraser, M.A., M.D. Aberd., received the honorary degree of LL.D. The same afternoon Lord Aberdeen presided over a meeting held for the furtherance of the extension scheme of the University, and a resolution was adopted whereby a fresh and vigorous movement will be inaugurated with a view to the completion of the buildings and the fuller equipment of the University. In the evening of the same day a brilliant company of about 1000 people was treated to a reception by the principal and professors in the Mitchell Hall. On April 10th the half-yearly meeting of the University General Council was held, and on the 11th there took place the annual meeting of the University Endowment Association, when encouraging reports were presented. The plans of new Greyfriars Church have now been approved by all the bodies concerned.—For the proposed memorial to the late principal, Sir W. D. Geddes, a sum of £950 has been subscribed, and it has been agreed to provide a medallion portrait in marble and a Geddes collection in the University library of works in classical literature and archæology.

Greenock Infirmary.

The following appointments have been made: Dr. J. Nairn to be a visiting physician, Dr. W. S. Cook, to be a visiting surgeon, and Dr. Eric Wilson and Dr. Edward Mackay to the medical staff of the out-patient department.

April 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

New Richmond Surgical Hospital, Dublin.

HIS Excellency the Lord Lieutenant has signified his intention of opening the new buildings of the Richmond Hospital on April 20th. They are now completely furnished and ready for the reception of patients, the number of beds at present available being 84, while the scheme allows for considerable extension in the future should the necessity arise. One of the principal features in the hospital is the operating theatre block which is probably one of the most complete of its kind in the United Kingdom. The theatre itself, apart from the various rooms devoted to the administration of anæsthetics and the sterilisation of water, instruments, &c., is a lofty chamber measuring 29 feet long by 23 feet wide. As in the new hospital in Liverpool the ventilation and warming are on the "Plenum system." The cold air is drawn through an air filter of cocoa-nut fibre, over which a spray of fresh water is continually flowing. It is warmed by passing over a calorifier heated by steam, and is then driven by means of a powerful electric fan into the theatre in any required volume and temperature. The vitiated air is extracted by means of a second fan and the whole apparatus is said to be capable of renewing the air of the theatre in the space of three minutes. As to the new wards they are all of the same size, with the exception of those for children—viz., 60 feet by 25 feet by 14 feet.

The Dublin Veterinary College.

The new Dublin Veterinary College, in which Sir Christopher Nixon as its first president takes such a strong interest, progresses favourably under the direction of Professor A. E. Mettam, D.Sc. There are now over 30 students attending its first session at the temporary premises, formerly the Hammersmith Iron Works. It is confidently expected that the new college buildings, which are to cover over an acre of ground in Pembroke Township, will be sufficiently advanced for occupation next year, and that the Veterinary College of Ireland will prove when completed to be one of the finest in the kingdom.

Royal College of Surgeons in Ireland.

At a meeting of the Fellows of the Royal College of Surgeons in Ireland, held on April 15th, Dr. R. Lane Joynt and Dr. P. W. Maxwell were elected members of the council.

North of Ireland Branch of the British Medical Association.

The spring meeting of this branch was held in the Museum, Belfast, on April 11th, the President (Professor J. W. Byers) being in the chair. The President and Dr. J. Tennant read notes of a case of Fever following Child-birth due to Infection of the Genital Tract with the Pneumococcus (Diplococcus of Fraenkel), with details as to the condition of the blood and of the Bacteriology of the lochia.—Professor T. Sinclair reported upon a case of successful Splenectomy and showed the organ removed. This is the second successful case of this nature shown to the North of Ireland Branch, the first having been operated upon by Dr. T. S. Kirk.—Dr. John Campbell read a paper on Retro-peritoneal Hysterectomy with illustrative cases.—Dr. Mandall Byers read notes of a case of Widal's Reaction during Secondary Syphilis.—Mr. G. L. St. George showed a case of Excision of the Elbow of exceptional interest.—Dr. S. T. Beggs and Dr. W. Calwell read notes of a case of Chronic Diarrhœa due to Tuberculous Disease of the Cæcum, and Dr. A. B. Mitchell gave details of the operation performed to relieve the condition—cæcectomy.—Dr. W. Calwell read short notes of (1) a case of Dilatation of the Stomach due to Pyloric Cancer (operated on by Dr. A. B. Mitchell); (2) a case of Cancer of the Cardiac Opening of the Stomach (operated on by Dr. Robert Campbell); (3) two cases of Dilatation of the Stomach in men over 50 years of age, probably due to Pyloric or Duodenal Cicatricial Stenosis; (4) a case of Extensive Adhesion of the Stomach leading to great wasting (operated on by Dr. T. S. Kirk); and (5) a case showing sequence of events—Migraine, Sleepy Dyspepsia, Seborrhœa Capitis, and Rosacea.—Dr. Howard Sinclair showed a case of Pulmonary Tuberculosis in a man. The bacillus tuberculosis had remained absent for three months after sanatorium treatment.—Dr. R. J. Johnstone showed several Pathological Specimens from the pathological laboratory.

Presentation to Dr. E. C. Bigger.

At a meeting in the City Hall, Belfast, over which the Lord Mayor presided, Dr. E. C. Bigger, who was formerly an alderman of the Belfast City Council and physician to the Fever Hospital, was presented by his friends with an illuminated address, a silver salver, and a silver rose-bowl on his leaving Belfast to take up his new appointment as Local Government Board medical inspector.

April 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

On a Parasite which has been observed in Syphilitic Patients.

AT the meeting of the Academy of Sciences held on March 25th M. Stassano read an account of a new parasite which he had observed to exist in syphilitic patients. In examining the blood-stained serum which was withdrawn by puncture from the enlarged glands accompanying a syphilitic chancre he noticed some motile bodies, apparently flagellated infusoria, belonging to the monad group. They were round, ovoid, or pyriform and had two flagella, the one straight at one pole and another at the other pole which was much longer and tortuous. In some instances M. Stassano was able to demonstrate a nucleus. These protozoa are, as a rule, free among the cells and leucocytes of the lymphatic tissue, but sometimes they are found attached to the blood corpuscles in the gland. They therefore penetrate into the circulation, but in the early period of syphilis they are very few in number and are found almost exclusively in blood drawn from the border of the lymphatic region which is first contaminated. Little by little they invade the greater circulation and multiply very rapidly by budding. The individual protozoa so formed sometimes remain collected in masses, but at a more advanced stage of infection—i.e., when the eruption is fully out—they separate and attach themselves to the corpuscles. At the same time they grow from either end, which gives them the appearance of trypanosomata, which also, as is well known, attach themselves to the red blood corpuscles. M. Stassano has not yet been able to follow the complete evolutionary cycle of this infusorium, but he is able to state that in the patients whose cases he has studied they are only found coincidently with the appearance of the rash and that they disappear on the patient getting better, whether this amelioration be spontaneous or due to drugs. The biological conditions of this parasite explain the diminution in the number of red blood corpuscles and in the amount of hæmoglobin which is observed at every exacerbation of syphilis, as well as the extreme fragility of the red blood corpuscles which has been noticed by Murri as existing in syphilis.

Serious Occurrence due to Carelessness at a Hospital.

The error of an attendant at the Lariboisière Hospital has brought about the death of one patient and exposed others to serious risk. Dr. Duguet prescribed for a certain number of patients an enema of honey and glycerine. The attendant, however, mistook the bottles and used one containing a solution of chloride of zinc which was kept for disinfecting purposes. After the enemata had been administered six patients were seriously affected and one died on the following day after terrible suffering. The attendant was removed from her office and punished, but Dr. Duguet lays all the responsibility for the accident on the direction of the hospital, for the zinc chloride should never have been mixed up with vessels containing solutions for *tisanes*, enemata, and the like, especially as there was no distinguishing mark upon the bottle containing it. Dr. Duguet himself did not even know of its existence in the ward. Why only one patient died is explained by the following facts. The attendant, finding that her bottle of glycerine did not contain enough, intended, so as to save the trouble of going over to the dispensary, to fill it up with water. For this purpose she took the bottle containing the chloride of zinc under the impression that it contained distilled water. It did not mix with the glycerine, and consequently the patient who died was given an enema consisting of pure chloride of zinc. The others escaped owing to admixture having presumably taken place through the disturbance of the fluid caused by the giving of the first enema.

Mosquitoes in Paris.

M. Debove, in discussing this question before the Academy of Medicine, entreated his colleagues to ask the public authorities for some measures of protection against mosquitoes. These insects during the months of July and August are the source of much inconvenience in many quarters of the city. It is true that up to now they have not been proved to transmit diseases of a grave character, for the particular variety which is a carrier of malaria has not so far appeared in Paris. But those which do exist are the cause of great discomfort, especially to those who live in the well-to-do quarters near the parks or where the mosquitoes find pools and puddles of stagnant water. In these puddles the mosquitoes breed and in 1898 the Committee of Hygiene of the Seine recommended a certain number of preventive measures to be carried out such as the suppression of pools of stagnant water or at least the treating of such pools with a small quantity of petroleum. M. Laveran, whose well-known researches upon intermittent fever have made him an expert in this matter, has associated himself with M. Debove. He considers that it is very disagreeable to be obliged to use, in the heart of Paris, a mosquito net as in tropical countries, if a good night's rest is desired. All collections of stagnant water should be rigorously dealt with, however small they may be. He pointed out that even a bucket filled with water and left in a courtyard would supply a breeding-ground for a number of mosquitoes sufficient to infest a large group of houses. If buckets are carefully emptied the development of the mosquito is put an end to. In squares and public and private gardens there should be no collections of water but only running water, in which the larvæ are unable to develop. If a reservoir of some kind is indispensable it should be closely covered so that the mosquitoes cannot lay their eggs in the water, and if by chance some larvæ should appear they can easily be destroyed by pouring a thin film of petroleum on the surface of the water.

April 16th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Syphilis.

DR. HEUSS, lecturer on dermatology at the University of Zürich, has just published his views on this important subject, and though doubtless they will encounter opposition, they are of interest and worthy of due consideration. The following is a short *résumé* of his paper which appeared, in the *Correspondenzblatt für Schweizer Aerzte*, 1901, No. 6. The treatment of syphilis in the initial stage is useless, nay, even harmful. Mercurialisation never acts as a preventive against syphilis, and that for the reason that mercury is a specific only for syphilitic symptoms but not for the syphilitic poison. This bears all the more weight as the diagnosis of syphilis in the primary stage is often impossible and mistakes are not uncommon. Dr. Heuss cannot recommend excision of a primary ulcer even in the earliest stage for therapeutic purposes. He adduces a case in which he excised a tiny wound 10 hours after syphilitic contact and yet syphilis developed in due course. Many other cases can be referred to, such as those recorded by Mauriac Gibier, Lang, Leloir, Wolf, Berkeley Hill, Havas, and others. Only in exceptional cases, such as those which are accompanied by very acute symptoms or complicated by iritis or rapidly increasing ulceration, can he recommend mercurial treatment in the first stage. Dr. Heuss is opposed to chronic intermittent treatment of syphilis for years as recommended by Fournier, as it acts detrimentally on the general health and does not prevent either recurrence or tertiary symptoms. He advocates energetic symptomatic mercurial treatment in the second stage of the disease, to be repeated if symptoms recur.

Bacillus Coli Communis in the Throat.

Dr. Joh. Seitz of Zürich has published a full description of a case of diphtheritic sore throat terminating fatally and due to infection with bacillus coli communis. The illness commenced with a rigor and a temperature of 103° F. Next day the temperature was from 103° to 104° and there was redness of the pharynx and tonsils. On the third day a white adherent thin membrane developed on one tonsil and spread to the other one, the temperature falling to 99° and the pulse rising to 102. The subjective symptoms were those of quinsy rather than of diphtheria, whereas the clinical symptoms corresponded to diphtheria. The glands were scarcely enlarged; the irritation in the throat with salivation and retching was great. The patient was very restless and the case terminated in syncope and sudden death. The bacteriological evidence pointed to bacillus coli communis as the cause of this fatal case of tonsillitis, no diphtheria bacilli developing in the numerous cultures that were made; unfortunately no post-mortem examination could be obtained. Dr. Seitz has never observed a similar case, though he has examined bacteriologically some 400 throat, nose, and ear cases. The assistant at the bacteriological laboratory of the University who makes all the examinations of presumed diphtheritic cases said that the occurrence of *abundant* bacillus coli communis was very rare in the 6000 cases which he has examined. The drains in the house of the patient, whose bedroom adjoined the water-closet, were out of repair and nauseous smells were often observed in the bedroom—a fact which throws light on the etiology of the illness.

Precautions against Plague.

Following the example of the German authorities the Swiss Federal Council has summoned to Berne such of the professors of hygiene and bacteriology and their assistants as can be spared for the purpose of attending a course of lectures and demonstrations. Hygienists of note consider that there is great probability of a spread of plague to Europe during the ensuing summer, and are of opinion that the European Governments should do all in their power to promote prompt diagnosis of the first cases of the disease in order that measures of isolation may be adopted.

April 13th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Emergency Hospital at the Buffalo Exposition.

A HOSPITAL has been erected in the grounds of the Exposition which is to be opened in Buffalo in May. The building has been constructed for the purpose of treating any person who may be injured or taken ill while at the Exhibition, and it is besides a picturesque feature in itself and is in harmony with the general plan of architecture followed by the designers of the Exposition. It is after the style of an adobe mission-house; it has a frontage of 90 feet and the main wing has a depth of 38 feet, with a height of but one storey except in the centre where is placed a square tower with a rounded top. A rear wing one storey high runs back from the centre portion to a distance of 56 feet with a width of 32 feet. The first floor front contains in the extreme western wing two male wards with seven cots each. The eastern wing contains a female ward large enough to hold a dozen cots. The upper storey is intended for the use of the resident physician and attendants. The building throughout is equipped with th[illegible] appliances and water, gas, an[illegible] very part of the building. Dr.

Anti-spitting Movement in New York City.

The Public Health Department of New York City have now for several years issued regulations as to promiscuous expectoration. The fact is generally recognised that the habit is not only extremely filthy and disgusting but that under certain circumstances it may be attended with serious danger to the health of the entire community. The aforesaid regulations apply to public buildings and conveyances, and the infringement thereof renders the offender liable to a heavy fine or a term of imprisonment or both. Latterly small heed has been paid to these orders, and owing to the law not having been enforced against those breaking them they have fallen into disrepute. The consequence of this laxness on the part of the authorities has resulted in a recrudescence of the spitting habit in public places, and especially in the street cars, to the great detriment and annoyance of all decent persons. Now, however, an official crusade is being waged against individuals who, careless of the comfort and health of others, deposit their sputum upon the floors of public buildings and vehicles. By the order of the President of the Board of Health a number of policemen from the sanitary squad, attired in plain clothes, are detailed to ride up and down Greater New York in the elevated trains and street-cars for the purpose of detecting and taking into custody any person of whatever age or sex found expectorating in such conveyances. On the first day when policemen were detached for this duty no less than 19 arrests were made, all of those arrested when brought before a magistrate being heavily fined. The President of the New York City Board of Health declares it to be his intention to keep the entire sanitary squad at work in enforcing the expectoration section of the sanitary code until the people of New York become definitely convinced that sanitary laws were made to be enforced.

Plague in San Francisco.

At last the question as to whether plague has been, and is still, present in San Francisco appears to be decided once and for all. For a long time—in fact, from the time the disease first broke out in San Francisco (as told in a former letter)—there has been friction between the United States Marine Hospital Service officials and the State and municipal authorities. The Governor of California has consistently denied that the findings of Dr. Kinyoun and coadjutors were correct with regard to their assertions that plague was present in the Chinese quarter of San Francisco and he has made use of his position to place obstacles in the way of a thorough cleansing and disinfection of that unsavoury quarter. Unfortunately, too, his contentions have been supported by one of the principal medical journals of the State. Now, however, an explicit statement setting forth the exact conditions of the plague situation in San Francisco has been prepared for the official public health bulletin in which it is shown that there have been 10 deaths from bubonic plague in San Francisco between Jan. 1st and March 15th. The statement says that of the cases reported in February six cases and deaths between Feb. 5th and 12th were reported by the special commissioner appointed by the Secretary of the Treasury to examine into the conditions regarding the plague in San Francisco. This commission consisted of Professor Simon Flexner of the University of Pennsylvania (chairman), Professor F. G. Novy of the University of Michigan, and Professor L. S. Barker of the University of Chicago (recorder). Plague has been reported in San Francisco officially in the public health reports since March 6th, 1900, 32 cases (all fatal) having been reported and published in the previous minutes of the public health reports, and the facts were reported in the annual report to Congress of the Secretary of the Treasury dated Dec. 4th, 1900. On the return of this committee to San Francisco Surgeon White wired on March 22nd that they had agreed to raise funds for immediate work to disinfect all infected houses, to provide hospitals for suspects, a detention house, and a morgue, and for the general disinfection of Chinatown, with betterment of light-space and air-space. Subsequent telegrams show that the work is being organised. The disease has been confined almost exclusively to the Chinese population, and an examination of the mortuary records of the latter for the past four years shows that there has been no time during that period when it has increased to such an extent as in itself to cause alarm. It is well that the National Government has interfered in the matter, and it seems somewhat of a mistake that this step was not taken sooner. If the extirpation of plague in San Francisco means the purification of Chinatown the disease will after all have proved "a blessing in disguise." With the drastic measures recommended from Washington it may be anticipated with confidence that plague will soon be driven out of San Francisco.

April 9th.

Obituary.

GIULIO BIZZOZERO.

FEW men within the comparatively brief term of 55 years have done sounder or more diversified work than Dr. Giulio Bizzozero, professor of general pathology in the University of Turin. Born at Varese in Lombardy on March 20th, 1846, he distinguished himself in classical study at Milan before matriculating at the University of Pavia. There he crowned a brilliant curriculum by taking the "summi in medicinâ honores" in 1866 and was just entering the path of clinical instruction when the outbreak of hostilities with Austria called him, like many other young graduates, to fight for his country under Garibaldi. A few weeks, however, sufficed to bring Austria to terms; Venice was ceded to the House of Savoy and the summer of the same year saw young Bizzozero, bronzed, if not flushed, from the successful campaign, once more absorbed in medical study—filling, indeed, at the age of 21 years the chair of general pathology just vacated by the transfer of Paolo Mantegazza to Florence. The young professor was effective and popular from the first, but he had too high a standard of proficiency to rest satisfied with what Italy could then impart to him. So the close of the session found him at Berlin working in the laboratory of Virchow, working, moreover, with an intelligence and an energy that drew from his great teacher a compliment he never forgot: "Bizzozero, il mio migliore allievo" (Bizzozero, my best pupil). And thus between Pavia and Berlin he continued to perfect himself, till in 1873, when but 27 years of age, he obtained by competitive examination among a host of formidable candidates the professorship of general pathology in the University of Turin, where, with ampler resources and more stimulating opportunities, he began the special studies which have left physiology and pathology so much the richer.

The mere titles of his monographs read before the Turinese Academy of Medicine and afterwards communicated to the sister academies or associations of the world will suffice to show the range and minuteness of his work: "Comparative Studies on the Nemaspermi and the Vibratile Cilia," "On the Automotor Corpuscles," "On Some Alterations in the Lymphatics of the Brain and Pia Mater," "On the Parenchyma of the Pineal Gland," "On the Relations of Tuberculosis of the Dura Mater," "On the Lymphatics and on the Structure of the Serous Tissues in the Human Subject," "On the Transfusion of Blood into the Peritoneum," "On the Production of the Red Globules in the Various Classes of the Vertebrates," and "On the Microphytes of the Normal Epidermis in Man." Not one of these memoirs is less than a model of painstaking, sure-footed induction, while the knowledge so laboriously and honestly acquired he had the art of communicating to young minds with an attractive power and an impressiveness which rewarded the attention he had so skilfully economised. His class-room and laboratory by this time were thronged with pupils from every part of Italy and not a few from abroad—indeed, scarcely a medical school in the Peninsula and islands is without one or more of his assistants on its professorial staff. Be it enough to mention Golgi of Pavia, Manfredi of Pisa, Bassini of Padua, and Bozzolo and Foà of Turin. According to one of these he had, in addition to his rare inductive power, "a lucidity of thought and of expression which reminded his hearers of the English orator."

His constant, his indefatigable work with the microscope had of late years begun to tell on his eyesight, and by the advice, nay, the gentle constraint, of his colleagues he abandoned its use, only, however, to throw himself with fresh energy into a field on which he has left a salutary and enduring mark—State Medicine. "As Beethoven," says a Piedmontese colleague, "after he became deaf still continued to compose, so Bizzozero, with eyes too weak for laboratory work, did not cease to enrich the healing art with masterly contributions." His ardent wish was to help on the regeneration of young Italy, first physically, then morally, inspired as he was by D'Azeglio's saying: "We have made Italy; we have now to make Italians." With this object he laboured hard with Celli and others to limit and finally to stamp out malaria, to antagonise and ultimately to prevent infectious disease, and, as provisional or collateral expedients, to cheapen pure quinine and to regulate the manufacture of serums. In not a few of these undertakings he encountered opposition and incurred controversy, particularly over that "quæstio" so needlessly "vexata"—vaccination. From the first a convinced and enthusiastic promoter of the Jennerian prophylactic, it is mainly due to him that Italy has not fallen a victim to the mischievous propaganda which of all places in the world has its starting-point in England. But his admirable inductive power, aided by a dialectic skill and a lucidity of exposition which his antagonists could not countervail, always left him master of the field. His last work, addressed partly *ad populum*, partly *ad clerum*, was on the etiology and prevention of cancer, now more frequently met with everywhere, Italy included; and he had barely given it to the press when he was struck down with the pneumonia which ever since the "new influenza epidemic" has found, especially in the Italian subject, an easier prey. By the eighth day of its course his resisting power was obviously at an end, and in spite of all loyal old pupils like Golgi, Fcà, Bozzolo, and others gathered round his bed could do he passed away at 8.45 P.M. on April 8th. *Consummavit cursum, fidem servavit;* and a public funeral of exceptional magnitude and solemnity has just attested the grief of his colleagues and compatriots on account of the loss of all that is buried in the grave of Giulio Bizzozero.

IVOR AJAX LEWIS, M.R.C.S. ENG., L.R.C.P. EDIN., J.P.

MR. IVOR A. LEWIS of Cymmer, Porth, died suddenly in the Glamorganshire County Club at Cardiff on April 8th. He had visited the town for the purpose of playing golf at Porthcawl, and returning to the club had not been long at dinner when he was seized with pain and shortly afterwards expired. Dr. Herbert Vachell, who made a post-mortem examination, stated at the inquest, held on April 9th, that death resulted from failure of the heart's action brought on by distension and congestion of the stomach after eating mussel soup, and a verdict was returned to that effect. Some other diners who partook of the soup were in no way affected by it. Mr. Lewis was born at Llantrisant in 1848 and was educated at Bristol Grammar School. He received his medical education at Guy's Hospital and took the qualifications of M.R.C.S. Eng. and L.R.C.P. Edin. in 1875. He commenced practice in Llantrisant and later removed to Abergorky, and 25 years ago he was appointed medical officer to the Cymmer Collieries. Mr. Lewis was also surgeon to the National Collieries at Wattstown. He was awarded in 1877 the bronze medal of the British Medical Association, and was a Justice of the Peace for the county of Glamorgan. Mr. Lewis excelled in many branches of sport. He was an excellent shot, had played cricket for his county, was a formidable opponent at billiards, tennis, and rackets, and was an enthusiastic golf player. He leaves a widow and a family of five sons and six daughters, for whom much sympathy is felt.

Medical News.

UNIVERSITY OF BIRMINGHAM.—At the First Examination for the degree of Bachelor of Medicine and Bachelor of Surgery, held in April, the following candidates passed in the subjects indicated:—

Elementary Biology (Part 1.)—Class I.: Robert Wallace Aitken, William Cook, Alfred Ernest Remmett Weaver, and Frederick Wilkinson. *Class II:* Reginald Hudson Astbury, John Staines Austin, Edwin Lancelot Bunting, Herbert Elwell, Helen Gertrude Greener, Edith Dora Grove, Cuthbert Keay Gettings, Harold Salter, Leonard Leigh Hadley, Richard John James Hawkes, Lionel Chattock Hayes, William Claude Horton, William Cuthbert Houghton, Ernest Henry Kenderdine, Leonard George Joseph Mackey, Vivian Gray Maitland, Henry Percy Pickerill, Horace John D'Arcy Gerrard Price, George Rollason, Norman John Lancelot Rollason, Henry Philip Thomason, Spencer Graham Walker, Bernard Joseph Ward, John Wells, and Edmund Stanley Whitcombe.

Chemistry and Physics (Part 2).—Class I.: William Cook, Cuthbert

Keay Gettings, Richard John James Hawkes, Thomas Holmes Ravenhill, Henry Philip Thomason, Alfred Ernest Remmett Weaver, and Frederick Wilkinson. *Class II.:* Herbert Elwell, Harold Salter Gettings, Joseph Richard Ewart Heseltine, Leonard George Joseph Mackey, Ernest Osborne, and Bernard Joseph Ward.

UNIVERSITY OF DURHAM.—At the first examination for the degree of Bachelor in Medicine held in April the following candidates satisfied the examiners:—

OLD REGULATIONS.

1. *Chemistry, with Chemical Physics.*—Thomas Hill Bailey, L.S.A., King's College Hospital, and John George Hugh Lane, M.R.C.S., L.R.C.P., Guy's Hospital.

NEW REGULATIONS.

1. *Elementary Anatomy and Biology, Chemistry, and Physics.*—Dudley Thomas Birt, College of [illegible] John Arthur Bell, St. Barthelor [illegible] Henry Hugh Croudace, Robert [illegible] Raffle, Robert Rutherford, and Ro[illegible] Medicine, Newcastle-upon-Tyne.
2. *Elementary Anatomy and Biology.*—Herbert Christal and John [illegible] College of Medicine, Newcastle-upon-Tyne.
3. [illegible]
4. [illegible] and Cook's School of Anatomy.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Honorary Degree of Doctor of Laws (LL.D.).—Angus Fraser, M.A., M.D., Aberdeen.

Degree of Doctor of Medicine [illegible] C.M., Brierley Hill, Staffs.; [illegible] es [illegible], M.B., C.M., Harbury, [illegible] ner, M.B., C.M., Beechworth, [illegible] under old regulations].

* Thesis considered worthy of commendation.

Degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) (Old Ordinances).—Tarcisius Bromilow, Lostock Park, Bolton, Lancashire; Daniel Albert Robert Farquharson, Ballater, Aberdeenshire; Walter James Flett, Findochty, Banffshire; and George Ernest Hugh Le Fanu, Aberdeen.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) (New Ordinances).—†Robert Aird, M.A., Peterculter, [illegible]

† Passed final examination with distinction.

Degree of Bachelor of Science (B.Sc.).—James Addison, M.A., Whitehills (with special distinction in mathematics and natural philosophy); Charles Todd Andrew, Hamilton; Charles Lyall Grant, M.A., Aberdeen (with special distinction in botany); Francis William Gray, M.A., Aberdeen; Arthur H. Mackenzie, Inverness; George Stewart, M.A., Aberdeen, Alexander S. Third, M.A., Aberdeen (with special distinction in chemistry); and Henry Alleyne Varty, Penrith.

Diploma in Public Health.—Norman Davidson, M.B. (Aberd.), Aberdeen; John Charles Galloway, M.A., M.B. (Aberd.), Oyne, Aberdeenshire; Alexander Ledingham, M.A., M.B. (Aberd.), Boyndie, Banff; Charles Murray, M.A., M.B. (Aberd.), Aberdeen; ‡James Ritchie, M.D. (Aberd.), Aberdeen; Alexander MacGregor Rose, M.B. (Aberd.), Aberdeen; Henry Sinclair, M.B. (Aberd.), Cults, Aberdeen; and ‡Alexander Brown Walker, M.B. (Aberd.), Aberdeen.

‡ With credit.

ARTIFICIALLY COLOURED SUGAR.—The public analyst for the county of Gloucester reports that during the quarter ended March last 121 samples of food, &c., were analysed of which 10 were adulterated. Six samples of sugar sold as Demerara sugar consisted of white sugar crystals coloured with a coal-tar dye.

AT the meeting of the Exeter City Council held on April 10th it was decided that Mr. C. E. W. Bell, the police surgeon, should in future receive 10*s.* 6*d.* per man with 3*s.* 6*d.* for the examination of each recruit instead of an annual salary of £30. The increase of salary was granted in consequence of the enlarged radius in which members of the police force now reside.

THE Corporation of London has contributed 100 guineas towards the purposes of the forthcoming British Congress on Tuberculosis in July next.

ON April 16th Mr. John S. Crone, L.R.C.P. Irel., J.P., of Kensal-rise, was re-elected chairman of the Willesden District Council for the ensuing year.

MEDICAL MAGISTRATE.—Mr. Justin McC. McCarthy, M.D. Durh., of St. George's, Salop, has been appointed a Justice of the Peace for the county of Salop.

VAGRANCY IN DORSETSHIRE.—Captain Granville, the chief constable of Dorset, has reported that there were 13,133 admissions to casual wards during 1900—a number fewer by 2617 than in 1899. This was a decrease of 27 per cent.

THE TENBY MEDICAL OFFICER OF HEALTH.—Mr. John Griffith Lock, owing to ill health, recently resigned the position of medical officer of health of the borough of Tenby. He had been annually re-elected since 1872 and was the oldest medical officer of health in Wales and, with possibly one exception, in the United Kingdom.

LITERARY INTELLIGENCE.—Messrs. J. & A. Churchill are issuing this week the sixth edition of Dr. Hale White's Materia Medica. The feature of this edition is that it contains the Materia Medica, Pharmacy, Pharmacology, and Therapeutics of the Drugs in the Indian and Colonial Addendum (1900) to the British Pharmacopœia, 1898.

THE POST OF PUBLIC ANALYST FOR THE CITY OF LONDON.—The Society of Public Analysts has laid stress on the importance of this forthcoming appointment by a letter addressed to the Corporation expressing regret at the terms offered by the Corporation, which, in the opinion of the society, are most inadequate, particularly with respect to analyses of water. The society also takes exception to the encouragement given to a system of competition among professional chemists without regard to a suitable equivalent for their services.

BOOKS, ETC., RECEIVED.

BAILLIÈRE ET FILS, Paris.
Royat: Indications Thérapeutiques méthodiquement classées. By Dr. A. Bouchinet. Price 2 francs.

BLACK, ADAM AND CHARLES, London.
Jerusalem: a *Practical Guide to Jerusalem and its Environs.* By E. A. Reynolds-Ball, B.A., F.R.G.S. Price 2*s.* 6*d.*

CARRÉ ET NAUD, Rue Racine, Paris.
La Grossesse Étude sur sa Durée et sur ses Variations. By Dr. L Bouchacourt. Price not stated.

CLAY AND SONS, Ave Maria-lane, London.
Science and Mediæval Thought. By T. Clifford Allbutt, M.A., M.D., &c. Price 2*s.* 6*d.*

GREEN AND SONS, Edinburgh.
Encyclopædia Medica. Vol. vii. · Liver to Menopause. Price not stated.

HIRSCHWALD, AUGUST, Unter den Linden, Berlin.
Die Herzkrankheiten bei Arteriosclerose. By Professor Dr. S. von Basch. Price 9 marks.

HUBBS, G. O., Waterloo, Iowa, U.S.A.
Transactions of the Iowa State Medical Society. Vol. xviii. Price not stated.

KEENER AND CO., Wabash-avenue, Chicago.
Human Placentation: An Account of the Changes in the Uterine Mucosa and in the Attached Fœtal Structures during Pregnancy. By J. Clarence Webster, B.A., M.D., &c. Price 3.75 dols.

KEGAN PAUL AND CO., Charing Cross-road, London.
Arsenic. By Professor J. Alfred Wanklyn, M.R.C.S. Price 2*s.* 6*d.*

KIMPTON, HENRY, Furnival-street, London.
Nervous and Mental Diseases By Charles S. Potts, M.D. Price 7*s.* 6*d.*
[illegible] By John Benjamin Nichols, M.D., and [illegible] Price 7*s.* 6*d.*
[illegible] Lincoln Ballenger, M.D., [illegible]

[illegible]reen, London, the [illegible]

[illegible] West Kensington, [illegible], the wife of [illegible] Robert Schofield, M.B. Lond., of a son.

MARRIAGES

DUN[illegible]

GIR[illegible] of Tonbridge Wells

MANNING—FLEMING.—On April 11th, at the parish church, Combe Martin, North Devon, by the Rev H. W. Toms, M.A., rector, and the Rev. F. W. Toms, M.A., N. S. Manning, F.R.C.S., L.R.C.P., Combe Martin, to Winifred Alice, only surviving daughter of Veterinary Colonel G. Fleming, C.B., LL.D., F.R.C.V.S., Principal Veterinary Surgeon of the Army (retired), Higher Leigh, Combe Martin

NEWMAN—YOUNG.—On March 21st, at Abbottabad, Punjaub, India, Captain Ernest Newman, M.D., I.M.S., [illegible]

FEP[illegible] Hall, near Liverpool.

WYLEY—METCALFE.—On A[illegible] Church, Leyburn, by the [illegible]y, assisted by the Rev. T. [illegible] the Rev. John Hawthor[illegible] K. Wyley, vicar of Hellor[illegible] J. Wyley of High Onn, Sta[illegible]ghter of Richard Metcalfe [illegible]

DEATH.

FORBES.—On April 6th, at Nice, William Forbes, M.R.C.S., late of Gippsland, Victoria, aged 69 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE CHURCH MILITANT FOR SANITATION IN HURDSFIELD"

IN THE LANCET of March 17th, 1900, page 817, some account was given of the very insanitary conditions which were allowed to prevail in Hurdsfield, a suburb of Macclesfield. Upwards of 700 houses in Hurdsfield were unsewered, streets were unpaved; a drain carrying sewage was in part of its course uncovered and at times most offensive; road gutters did not communicate with any drains but were fitted with dummy traps and grids; and the "ashpit system" was in vogue, the contents being apparently emptied into the street and then removed This objectionable state of matters, of course, could not exist except by the apathy of the Macclesfield Corporation. Hurdsfield, in fact, seems to be a working-class district—no alderman lives there; one of the residents is a councillor, but he is a recent importation. Notwithstanding the mediocrity of its position from the social point of view Hurdsfield has in its vicar—the Rev. William Laycock—a fearless champion of sanitation, possessed of a fluent pen This gentleman is as zealous for the bodily health as for the soul's health of his congregation, and in the April number of the *Hurdsfield Church Messenger* he justifies his attitude by a reference to the new Bishop of London who has said that God intended a bishop to look after sanitation. He has been unceasing in his efforts to obtain better sanitary conditions for the district, and when his representations had little effect on the Macclesfield Corporation he appealed to "higher authorities," one of which was, of course, the Local Government Board. Some of the results in the way of making sewer connexions, &c., are duly chronicled in the January number of the *Messenger*. A portion of Mr. Laycock's subsequent correspondence with the Local Government Board is published in the *Macclesfield Courier and Herald*, which also mentions that the supineness of the Health Committee is being criticised by another resident of undoubted position Clergymen of Mr. Laycock's energy and public spirit are aids to progress everywhere and their influence is especially beneficial in communities where there is no leisured class interested in local improvements.

RECREATIVE READING.

To the Editors of THE LANCET.

SIRS,—Will one of your reviewers tell me the names of a dozen good novels? Save for a few classics I have read no fiction. I have never had time to do so till lately Will you guide me in my choice and oblige, Yours faithfully,

RETIRED.

*** [illegible] need not answer anyone who asked him for [illegible] confectioner. Then he might decline to answer. We regret to say that that is what we must do.—ED. L.

"PLACE OF RESIDENCE FOR A RETIRED SURGEON."

To the Editors of THE LANCET.

SIRS,—I am able to inform your correspondent "P. P." in THE LANCET of April 13th, p 1118, that I have not found West Bournemouth or Branksome at any time very hot or relaxing, and I had previously to becoming a resident visited here several times, and from experience I should consider the western part of Bournemouth and its neighbourhood suitable for an eastern counties man.

I am, Sirs, yours faithfully,

F. H. A

April 14th, 1901.

THE TREATMENT OF THREAD-WORMS.

To the Editors of THE LANCET.

SIRS,—Will some of your readers kindly suggest a treatment for the following case? A female child, aged seven years, has suffered from "thread worms" for the last four years. All ordinary treatment (such as injections of quassia, salt, &c., with purgatives internally) has failed to cure the complaint. I am, Sirs, yours faithfully,

WORMS.

April 16th, 1901.

BLACKWATER FEVER

IN an article on Blackwater Fever published in the April number of the *Scottish Medical and Surgical Journal* Mr. S. W. Thompstone and Dr. R. A. Bennett state that as far as they can judge from the statistics of Southern Nigeria there is a well marked connexion between the particular season of the year and the number of cases of that disease recorded. Curiously enough, this connexion is the exact reverse of that which obtains in the German Cameroon Colony, although the seasons are practically the same in both tracts of country. F. Plehn, in his monograph on the diseases of the Cameroons, distinctly states that from the beginning of the rains in March to their termination in November the number of cases of blackwater fever steadily grows, to fall suddenly at the onset of the dry season. In Southern Nigeria, on the other hand, the disease is much more common during the dry season than during the rains. It is more frequently met with now than formerly and it varies very much in severity in different years. In one season a dozen cases will occur consecutively without a death, and in another the death-rate may be as high as 20 or 40 per cent. of the cases treated. In the great majority of cases there is no history which throws any light on the predisposing cause, though exposure in a certain number of cases appears to have been the exciting cause of the attack. No case has been recorded among natives in Southern Nigeria since the institution of Government statistics.

"THE SALT CURE."

To the Editors of The Lancet.

Sirs,—In reply to the letter of "S. W." in The Lancet of April 13th, p. 1117, in which he refers to an article in the *Contemporary Review* for March upon the treatment therein called "the salt cure," I should like to call his attention to the fact that the method of Dr. Jules Chéron was introduced to the notice of the medical profession in this country by Mr. Ralph H. Browne at the meeting of the British Medical Association at Clifton in 1894. About the same time Mr. Browne issued a *brochure* on the subject which was published by Messrs. Churchill, and which is, no doubt, still obtainable. The treatment therein described is undoubtedly of great value in many cases of neurasthenia and hysteria.

I am, Sirs, yours faithfully,

Chas. Lloyd Tuckey, M.D. Aberd.

Park-street, W., April 16th, 1901.

"UNPLEASANT ENTERPRISE."

To the Editors of The Lancet.

Sirs,—My head office have directed my attention to the observation under the heading of "Notes," contained on page 1118 in The Lancet of April 13th. After reading your remarks I have come to the conclusion that to a large extent your criticism is a just one, but I am bound to add that I had not the slightest intention of doing anything that would cast a reflection upon the parties referred to in the newspaper extract, and further, I do not think that I have done anything to extend the knowledge of the incident. My desire was simply to tell those who followed similar occupations that any financial risk involved could be covered by insurance, without recognising that the action in question was not raised in a civil court. I will also add that the issue of the letter and newspaper cutting was done on my own responsibility entirely and without the authority or even knowledge of my head office, who, I am bound to add, disapprove my action. I beg you will insert this communication in your next issue.

I am, Sirs, yours faithfully,

A. R. Aldred,

District Manager, Law Accident Insurance Society.

Leeds, April 16th, 1901.

THE EARLIEST PORTRAIT OF HER LATE MAJESTY QUEEN VICTORIA.

There are few households which do not possess some portrait of Queen Victoria. The usual likeness represents her in middle or advanced life, but a miniature showing her as she was when a very little girl is now being reproduced by Messrs. Waterlow and Sons, Limited, for Mr. V. O. Mallan of 106, Edgware-road, London. The miniature is tasteful and pleasing in appearance; it includes the face and upper part of the bust and is mounted in a black circular frame rather less than four inches in diameter. It is the earliest portrait and was formerly in the possession of the Duchess of Kent. In verification of its authenticity it is accompanied by copies of letters written on behalf both of the Queen herself and of the present King when Prince of Wales. On the reverse of the miniature there is a facsimile of a lock of the Queen's hair.

WANTED—A HOME.

To the Editors of The Lancet.

Sirs,—I should be grateful if any of your readers could let me know of a home where a young man who is suffering from diabetes mellitus could be taken in and could receive medical treatment. He can pay a small weekly pension. I am, Sirs, yours faithfully,

New Seaham, Durham, April 14th, 1901. E. J. Howley.

W. G. asks us what is the average cost of residence at Davos Platz for a case of pulmonary tuberculosis? The cost to a man to whom every shilling is of consequence would be very different from that to a man of ampler means. The ordinary patient at an English hotel will spend during his winter residence 20 francs a day, rather more than less, and the sum will include payment for milk, wine, and other obvious extras. For patients of smaller means there are cheap English pensions where the cost would amount to six or seven francs per day, while residence at a cheap Swiss pension would cost a little less than this. Our correspondent may like to know that there is at Davos Platz an invalid home open for ladies and gentlemen of small means where the payment of four to four and a half francs per day covers medical attendance and nursing.

HOSPITAL PRACTICE IN VIENNA.

To the Editors of The Lancet.

Sirs,—I should be glad to know if any of your readers could inform me as to the facilities for hospital practice at Vienna. I want to do some clinical work in medicine and surgery for an examination. I should also feel much obliged for any information with regard to the "coaching" in these subjects to be had there by someone who speaks English. I am, Sirs, yours faithfully,

April 17th, 1901. M. O. H.

Mr. E. J. Reid of 11, Dunedin House, Basinghall-street, London, E.C., has forwarded us a pamphlet relating to all that is known of vasogen and vasogen preparations. The pamphlet has been arranged alphabetically for ready reference by Dr. M. Gallas of Hamburg. The vasogen compounds are of undoubted importance in treatment by drugs and a number of interesting cases of their application are recorded in this pamphlet.

◆

Alienist.—A consulting physician expects to take a guinea as a minimum fee when asked by a brother practitioner to see a case. "Alienist's" proper fee seems to us to depend upon the duty required, the distance of the patient from his house, and the number of visits—points upon all of which we are in ignorance. We cannot suggest with the information before us what charges should be made.

T. J. J.—Professor Clifford Allbutt's article on "Opium Poisoning" in vol. ii. of "Allbutt's System of Medicine" will be found to give a very good account of the habit. There is no separate book so far as we know, but references are given at the end of Professor Clifford Allbutt's article to various papers which have appeared dealing with the subject.

Angina.—In the first position described by our correspondent B's attitude is quite correct. In the second we think he should himself have informed A that it was his intention to take over the treatment of the child on the understanding that the case had been given up by A. This would have given A a proper opportunity of explaining matters.

Eager.—The condition is one to which far too much importance is attached. Our correspondent should consult his family medical man.

G.P. is advised not to administer anæsthetics for an unregistered dentist.

Query.—The man is a complete impostor.

Communications not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months...	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris,

A Clinical Lecture

ON

THE SOMETIMES SUCCESSFUL TREATMENT OF CASES OF APPARENTLY INCURABLE BLINDNESS.

Delivered before the Nottingham Medico-Chirurgical Society on Nov. 21st, 1900,

By CHARLES BELL TAYLOR, M.D.,
F.R.C.S. Edin.,
HONORARY SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

Mr. President and Gentlemen,—It has been my good fortune on many occasions to restore sight to persons who were believed to be incurably blind, and as this end has been attained by means which are not usually adopted in the treatment of such cases it seems desirable in the interests of science and humanity that some mention both of cases and treatment should be placed upon record. Of course, it is not possible within the limits accorded to speakers on these occasions to do more than outline a few clinical histories, but sufficient will be said to show the vast importance of the subject and the marvellous results that may be now and then obtained. The cases comprise patients who have recovered after many years of apparently hopeless blindness, others who have suffered from, and under treatment have recovered from, the effects of neuro-retinitis, iritis with diffuse scleroderma, hyalitis, detached retina, atrophy of the optic disc, and the results of destructive inflammatory and degenerative changes. As to remedies outside the usual routine I should certainly place electricity, static, faradaic, and galvanic first; mercury, in large doses, either alone or in combination with other drugs second; derivatives, vascular, nervous, or both, third; and lastly, persevering treatment on these lines, with such operative procedures as may be indicated in each individual case, so long as there is the least chance of benefit or any eye left to be operated on. I propose to say a few words under each of these heads and to cite such cases as may serve to illustrate my meaning.

First, with regard to electricity, static, faradaic, and galvanic, I think that there can be no doubt that the profession is too much disposed to look askance at the employment of this remedy in the treatment of a variety of diseases; specially is this the case with regard to diseases of the eye; but the eye is really, from its watery constitution, its aqueous and vitreous humours, and consequent great conductivity admirably adapted for treatment of this kind; indeed, it is so easy to pass a current through the eyeballs along the optic nerves to the brain that one cannot but wonder why such obvious treatment should be neglected, while prominence is given to the administration of tonics and nerve stimulants which cannot possibly "touch the spot" as this remedy does and which have always failed to produce equally good results. I suppose this is due to the fact that those who are engaged in the treatment of diseases of the eye do not as a rule trouble themselves very much about electricity, while those in charge of the electrical departments of our great hospitals seldom or never see a case of eye disease; however that may be we must all acknowledge our great indebtedness to electricity, in the form of the Roentgen rays for instance, which, although it was discovered 40 years ago, has recently come upon us as a revelation, not only as an illuminant, but also as a therapeutic agent of the greatest value. Again, no one can fail to appreciate the charming results obtainable by electrolysis in angiomata, in inoperable tumours, adenoids, granular lids, and other abnormal growths. As a cautery, cataphoric agent, illuminant of internal cavities, destroyer of bacilli, heat and ozone producer, it is certainly without a rival, and the electro magnet, both as a sideroscope and extractive agent, is indispensable in the treatment of accidents which are of daily occurrence. Again, no doubt can be entertained as to the value of the galvanic and faradaic currents in case of corneal ulcers and opacities, neuro-paralytic keratitis, and in cases of paralysis, both partial and complete, of the ocular, facial, and other muscles; all this goes without saying, but I go further still. I claim for this subtle agent a potent influence upon living protoplasm, a restorative substitute, not only in cases of result of injury with its accom but also in neuritis and degenerative changes such as accompany and follow upon attacks of influenza, diphtheria, diabetes, typhus, typhoid, rheumatic, and other fevers; as a stimulant, tonic, and catalytic agent in these cases it is undoubtedly of the greatest value, and it is our *dernier ressort* in cases of atrophy of the optic disc, neurasthenia, asthenopia, failure of brain power, and general nervous declension, such as is observed at the menopause in women, or as a result of advancing years or exhausting diseases, or the abuse of alcohol, lead, and tobacco in persons of both sexes; of course, one cannot always succeed, that were to ask too much, but succeed or half succeed, or succeed not at all, you will, if you use this remedy, since hope is so potent a tonic, often do good in cases apparently beyond the reach of art, and now and then you will come across a case in which the effects are truly marvellous. Here is one. This patient, when 35 years of age, was sent to Nottingham in order that he might be taught a trade in the blind asylum; he had lost his sight in consequence of a severe attack of optic neuritis, and when I first saw him the discs were white and blurred and he could not tell night from day; he had been treated with the usual remedies without benefit and the case seemed hopeless. I nevertheless persuaded his friends to bring him to me daily, and sometimes twice a day, on which occasions I applied as powerful a galvanic current as could be borne. At first there was no change and I concluded that the case was hopeless; nevertheless, I determined to persevere a little longer and then improvement set in. First he saw the light, then a little more and a little more, day by day, until at last, to my great joy, I saw him one morning, with uncertain gait, stagger past my window without a guide. Sight continued to improve until he was able to resume his former occupation of coach painter and he can now (12 years later) read the newspaper in a bad light and his distant vision is perfect. This patient has been examined by eminent ophthalmologists and the traces of the disease from which he has suffered are still plainly visible. I have quite a number of cases which have been benefited by the use of the same remedy alone or in combination with other treatment. The list includes cases of hysteria, spinal amaurosis, amblyopia, amblyopia exanopsia, blindness or imperfect sight, the result of anæmia or simple atrophy of the disc, atrophy following on typhoid fever and other exhausting diseases, lead poisoning and the abuse of alcohol, tobacco, and some other poisons. The time at my disposal will not, however, permit of further details under this head and I therefore pass on to my next great remedy—mercury in large doses alone or in combination with other drugs. And here I must enter my protest against the very general impression that mercury *per se* (I mean in its non-corrosive forms) is a very dangerous poison; it is nothing of the kind, except in cases of idiosyncrasy, which one hardly ever sees, and in cases of defective elimination, which are rare; it is a comparatively harmless drug. Witness the workmen who were formerly, and I believe still are to some extent, engaged in silvering mirrors, and who were and are perforce more or less under the influence of mercury for years together. These men get high wages and so far as I can learn do not lead very careful lives, yet, although I have seen odd cases of neuritis, slight tremor, and occasional mild salivation among them, I have never been able to make out that they were as seriously affected by their occupation as they would have been if the very general impression as to the evil effects of this drug were correctly founded. I remember when I was a student a female out-patient at one of the London hospitals taking in one dose several ounces of mercurial ointment which had been prescribed in small quantities for external use; she was, of course, profusely salivated but was cured of her disease and seemed no worse afterwards. I believe the Arabian physicians, who were the first to use this remedy, prescribed it (principally in the form of ointment) in enormous doses, and we all know that in the old times a pint or more of saliva was exacted as a daily tribute from the inmates of lock hospitals, even when they were suffering only from non-syphilitic or pseudo-syphilitic affections. If I am told that I err in making these statements or that I have been misinformed, I reply, be it so, it does not affect my argument in the least, for I have put this question to the test myself fully in the persons of numerous patients who have been taking mercury when indicated, under my direction, sometimes for years together. I still see now and then a lady patient from a distance who owes her salvation to mercury which she has been taking in the form of blue pills, sometimes six times daily (with intervals), for many years, and I have numerous patients who have taken it for long periods with no ill-effects whatever. Meanwhile the influence for good of this much-abused remedy, alone or in combination, is simply marvellous; here is a photograph of a young lady, 15 years of age, from a neighbouring town who has been taking mercury in large doses for *four* years; when I first saw her she was quite blind from iritis and diffuse scleroderma, or, in other words, parenchymatous keratitis. No iris or pupil could be seen, in fact, the eyes were simply opaque masses; she had been under treatment by eminent specialists and the case was considered hopeless; nevertheless, she has recovered perfectly, her eyes are as bright as those of anyone, she sees very well indeed to read and at distance, and her health has distinctly improved. Here are other cases that may be taken in proof of my position. The first of these was a peer who had always been short-sighted; he had been attacked long before I saw him with irido-choroiditis, followed by effusion into the vitreous humour, in fact, it was impossible to illuminate the fundus in either eye; he had been treated with mercury in small doses and other alteratives *secundum artem* by the most eminent men of the day and was ultimately declared incurable. "We can do nothing for you, my lord"—a sentence doubly shocking to one who had all else which wealth could bestow. As it was impossible to light up the interior of the eye an accurate diagnosis was out of the question, but I was informed that there was probably detachment of the retina in both eyes. I treated him with galvanism, large doses of mercury, massage, pilocarpine, and derivatives, with the result that within a month he had recovered most excellent sight, as good as he had ever enjoyed in his life—a blessing which he retained in full perfection until the day of his death many years later. I have had three cases almost identical with the one quoted in each of which the patients recovered, and many others differing only in small details; of the former, one was a distinguished journalist, another was a well-known merchant, and the third was an actress. The last-mentioned patient had, in spite of treatment in the metropolis and elsewhere, been blind for two years when I first saw her; in this as in the other cases it was impossible to light up the interior of the eye; nevertheless, under treatment similar to that just recorded the cloud disappeared, and although the nerve proved to be partially atrophied she has recovered sufficiently to be able to resume her former occupation upon the stage.

Mercury may be administered in the form of the blue pill, ointment, vapour and sub-conjunctival injections. For the last purpose I prefer the cyanide, the injection of which may be rendered quite painless by the addition to the solution of a small portion of acoine. It is frequently necessary to combine morphia with the pills, and pilocarpine is an immense help. This last may be given in half-grain doses internally or used as a hypodermic injection in doses of from one-tenth to one-quarter grain; salivation and profuse sudation are caused, and it is necessary to guard the sufferer against cold by raised temperature of the sleeping apartment and plenty of bed-clothes. Another adjunct is elaterine, which causes profuse watery evacuations and is specially useful, in doses of one-fortieth to one-tenth of a grain, when in addition to other troubles there is detachment of the retina.

Let us see now what can be done in the way of derivatives, vascular and nervous, or both, and among these I must give first place to blood-letting. I am afraid you will think me very old-fashioned, but I am certain that we do not bleed enough in the present day. When I was apprentice to a country practitioner in this neighbourhood we used to bleed patients at their own request, and for no particular reason, or because it was the spring or fall or change of life, or something of that kind; and I have now in my possession an old daybook or diary belonging to another practitioner on almost every page of which you may read, "Iter venesectio." A friend of mine formerly practising at Oostock used to bleed himself whenever he felt unwell. Both his arms were scarred with the wounds of repeated venesections. He was over 80 years of age, and when I spoke on the subject, eagerly offered to perform the operation on his own person in my presence. We all know that in olden times the barber's pole betokened a willingness to bleed; indeed, in those days they thought no more of bleeding a customer than they did of shaving, hair-cutting, or selling liquor.

"Roam not from pole to pole,
But linger here,
Where you can be bled
And take your beer."

"Will you lose a little blood this morning, sir?" "No, thanks, I cannot spare the time." Now so violently are things changed that you cannot get bled if you wish to, not even if it would save your life. Some time ago I was taking a drive with a country practitioner and he asked me to see one of his patients with him. The patient in question was a full-blooded farmer about 50 years of age and weighing upwards of 16 stones. He sat bolt upright in a chair, the arms of which he grasped in desperate efforts to breathe. The pulse was laboured and he was as blue as a bilberry. "Bleed him," I whispered to my friend, "for God's sake, if you wish to save his life." He replied, "I have never bled a patient in my life." The farmer died the same night. A former patient of mine, of stout apoplectic build and subject to epistaxis (after a period of immunity from his usual loss), was seized with a violent pain in the head; he felt intuitively that he ought to be bled and called upon and besought three practitioners in succession to open a vein; they all refused and he returned home disconsolate, had a fit the same night, and died partially paralysed not very long afterwards. I hope you will agree with me that this is all wrong; the loss of a little blood, or a lot of blood for that matter, is of no great consequence, and if the patient is likely to be benefited he ought to have the chance of such benefit as blood-letting would afford; moreover, thick, treacly, diseased blood is better let out, and if the patient partakes freely of water it is diluted to his manifest advantage.

I remember a woman afflicted with delusions who murdered her three children and then cut her own throat, the last imperfectly. As the blood flowed her delusions vanished, the cloud lifted, and she at once realised and bitterly repented the awful crime which she had committed. Bleed early; *Obsta principiis* must be your motto, and let the blood flow until the pain, if there is any, has quite gone. When the eye only is affected it is difficult in the present day to persuade patients to submit to venesection, but I have applied 70 leeches to the temple in one case and have taken many ounces of blood with Herteloup's instrument from the same situation with the utmost benefit on several occasions. There are, however, other derivatives which act primarily on the nervous system, and which by diverting the *materies morbi* from the part affected often enable us to deal successfully with disease. These are sinapisms, blisters, setons, issues, ice-bags, hot-water bags, Turkish or lamp baths with hot pediluvia, intestinal derivatives, hot and cold aspersion, and the actual or electric cautery used so as to produce mere stimulation, counter-irritation, or destruction of tissue. Let me illustrate my meaning. When a man suffers from shock such as sometimes occurs on the introduction of the catheter, and this shock is so serious as to be followed by suppression of urine, he will die from uræmia and acute congestion if you cannot divert the attention of the nervous system from the kidneys to the skin. When a woman is seized with a rigor on the introduction of a foreign body into the uterus she will die from inhibition (as has happened in cases of criminal abortion) unless you can speedily distract the attention of the nervous system. When a delicate girl suffers from intense fright she is apt to develop palpitation and protruding eyeballs unless you can speedily distract the attention of the nervous system. See now what happens when the attention of the nervous system *is* distracted. When a man on the sea-shore afflicted with an urgent desire to micturate has stepped apart for that purpose the desire will instantly cease and remain in abeyance for hours if he finds himself surrounded by an advancing tide and his life is in danger; when an asthmatic on horseback is seized with a paroxysm of dyspnœa the attack is instantly arrested if his horse bolts and he finds it is as much as he can do to keep his seat; when a paraplegic afflicted with hysteria is roused by a cry of fire she will recover the use of her limbs and run down stairs, though she may have lain supine and helpless for months or even years. Note, epileptics when on horseback do not have fits; and we all know how the mouth dries up and the back aches on intense emotion; how pain is annulled by religious ecstasy and how the toothache vanishes when we knock at the dentist's door.[1]

Gentlemen, when the beet-root sugar industry in Germany was threatened with extinction through the ravages of a parasite termed the eelworm Professor Kühn saved the situation by planting a decoy vegetable alongside the roots, and we can do precisely the same thing in surgery. If a vital organ is threatened with extinction or serious damage by inflammation we can save it by establishing another inflammation in a less vital organ near at hand; the attention of the nervous system is distracted; nature cannot support the two inflammations—as one waxes the other will wane, as one grows the other will wither; and this is true to a certain extent even of malignant growths. What more simple, then, what more rational, when sight is threatened by an intense or chronic inflammation than to save the eye by establishing an irritation or serous or purulent discharge in the nape, in the temple, the arm, or elsewhere. Let me remind you that Mr. Pott used to cure paraplegia and ataxy by setons, issues, and other counter-irritants placed in the cellular tissue alongside the spine, also that patients suffering from pyæmia were often saved by the formation of artificial abscesses in the cellular tissue of the buttock, spine, or leg. Shakespeare tells us "that one fire burns out another's burning, one pain is lessened by another's anguish," and if one principle in the practice of our profession is more certain than another it is that one pus-forming centre, one inflammatory zone, will dry up another. Nature, I repeat, cannot support the two and the way to kill one is to foster the other; this principle was more frequently acted upon and better understood by our predecessors than it is by ourselves, and I regret to see that some authors and more practitioners scout the idea of counter-irritants and derivatives, and often refuse to employ one of the most useful remedies and one of the most potent means for good that we possess.

I now come to my fourth and last contention, which is simply this, that if you will treat patients on these lines—that is, if you will distract the attention of the nervous system by baths, derivatives, and counter-irritants, cut off the supplies of *materies morbi*, sugar, uric acid, indican, &c., by diet and depletion, stamp out the specific element of the disease, gout, rheumatism, syphilis, or what not, by specific treatment—and then resort to such operative measures as may be indicated in each individual case, such as the formation of an artificial pupil, the removal of inflammatory products, the extraction of the lens itself if necessary, and the cutting out of capsular débris if needful, you will restore sight in many cases where such a result seemed impossible. Here is one. The patient, resident in London, married, and 27 years of age, was seized a decade ago with irido-choroiditis in both eyes. Notwithstanding treatment the attacks recurred again and again, until four years ago the iris in both eyes was bound down and the pupils were blocked with lymph. She was treated by the most eminent ophthalmic surgeons and submitted to four operations, two in each eye, apparently without benefit, and as blindness was complete, the pain very great, and the case presumably hopeless, it was decided to excise the left eye; this operation the patient at the last moment refused and then came to me. When I first saw her inflammation was rampant in both eyes, and I therefore treated her with depletion issues and large doses of mercury—in fact, she was profusely salivated again and again much to her temporary discomfort but with the utmost benefit to her eyes; then, when all inflammatory troubles had ceased, when I had as I believed stamped out the essential element of the disease, I ventured to remove a mass of lymph and degenerate iris from the right eye, only to find, as so often happens in these cases, that the lens was quite opaque. I therefore performed the operation of extraction for cataract *secundum artem* upwards, leaving a clear pupil which I hoped would suffice for vision; but no, it became blocked with lymph and closed almost immediately; so I made another pupil only to be disappointed again by closure, and then a third, which last proved successful, and this lady, who had been blind for four years, has now excellent vision. Here is a letter from her in which she describes how much she enjoyed the sights in the crowd on the recent home-coming of the City Imperial Volunteers.

You will say, What became of the left eye, the one condemned to excision? Well, this eye was subjected to precisely the same series of operations with (incredible as it may seem) exactly the same result, in fact, she recovered excellent sight with it and writes, "I can now see very well with my left eye and my right improves daily."[2]

Here is another case which shows how things "out of hope may be compassed oft by venturing." This patient was in his twentieth year attacked with irido-choroiditis for which he was treated for three years as an out-patient and as an in-patient at one of our largest ophthalmic hospitals. Ultimately the retina became detached in both eyes and then cataract, secondary cataract, formed also in both eyes, so that when I first saw him the pupils were blocked with milk-white masses and he could barely tell night from day. I treated him with galvanism, mercurials, sudation and derivatives, and then, when his improved condition warranted the procedure, extracted the lens in each eye. He has now, as you see, very good-looking eyes and very useful vision, being able to earn his living as a journeyman baker.

Here is another very similar case occurring in a patient who has already been presented to the notice of the members of this society. This patient, who had been treated in an ophthalmic hospital, was sent to me by the late Dr. Metcalf of Lancaster. She was 22 years of age, had been blind for four years, and had during that period consulted several ophthalmic surgeons, with the result that she was declared incurable and was advised to enter an asylum for the blind without delay. "Is it any use going elsewhere for advice?" she asked. "Not a bit; no one can do you any good." When I first saw her both pupils were contracted, adherent to the capsule of the lens, and blocked by dense calcareous masses, while the eyes were so soft that they collapsed under the finger. I treated her with constitutional remedies *secundum artem*, with the continuous galvanic current and subconjunctival injections, and when her improved condition warranted the procedure I extracted the calcareous masses from each eye, with the result that she recovered excellent sight both for reading and distance; in fact, I have letters from her as well written as any I could write myself.

These cases, if neglected, overlooked, or deemed incurable, will often lead to many years of deprivation of sight, or even to life-long blindness, a catastrophe which may be averted by judicious treatment. Here are two or three cases which may be taken as proof of this assertion. The first is that of a lady resident in one of the northern counties who came to Nottingham to consult me in her sixtieth year. She had been blind for upwards of 30 years, during which time she had borne three children, not one of whom she had seen. It appeared that when about 30 years of age this lady, who was in affluent circumstances, was seized with an attack of irido-choroiditis in both eyes, which, although subdued by treatment, left considerable impairment of vision. This attack was followed by others, the sight deteriorated more and more, until at last she could not see to go about. At this time she was taken abroad to consult an eminent specialist and she remained on the continent for some months. Varying treatment was subsequently adopted both at home and abroad until she was brought to me. At that time the pupils were reduced to mere points and were blocked by dense masses of lymph; suffice it to say that I extracted the lens and operated upon her repeatedly until I at last succeeded in making an artificial pupil in the left eye, through which she was enabled to read, write an excellent hand, and walk abroad unassisted.

Here is another case that was brought to me by the Rev. Mr. Lloyd of Draycott, in this neighbourhood. This gentleman had been blind for upwards of 40 years and was habitually led about by an attendant. Both pupils were closed and blocked by dense calcareous masses which I managed to remove, and then by making an artificial pupil succeeded in restoring vision in the right eye. This patient recovered excellent sight, and was enabled to read and write and to go about with great facility. Another gentleman, the son of a Member of Parliament, who had been blind for upwards of 30 years and who had been habitually led about, also recovered under similar operative treatment sufficiently to travel as a "commercial," to see the time by his watch, and to go about unassisted. And I have quite recently (that is, within the last six months) had two similar cases—one recovering by operation excellent sight after a blindness of upwards of 37 years in the right eye, the other being very defective, and another from a similar condition, also by operation, which in one eye had existed upwards of 20 years. I perceive, however, that time will not permit of further details on this occasion and I therefore conclude.

---

[1] Witness King David, the orator's water bottle, the Indian ordeal for theft, the Flagellants, the Crucifixionists, and that extraordinary sect who submit to be buried alive.

[2] Owing to an accidental injury some months later this eye suffered a relapse which necessitated a further operation, with what result I cannot at present say.

Gentlemen, in dealing with disease you must remove the cause, strengthen the vital resistance, and treat symptoms as they arise, taking special care to do no harm. As Aristotle has it, "*Τό δε πρῶτον τό μή βλάπτειν.*" Indeed, no amount of success, however brilliant in certain cases, can compensate for failure and loss of sight in others if such failure and loss of sight is the result of the operator's overweening confidence, neglect of proper precautions, or unnecessary interference. You will note that I do not ask you to forsake the beaten path, to essay an impossible task, or to take a leap in the dark. I merely seek your adoption of plain common-sense principles, which everyone can understand, which have the sanction of experience and which yield important results. It has been well said that "to restore sight to the blind will ever be considered one of the grandest of human achievements." To restore sight to persons hitherto considered incurable is perhaps grander still; but best of all, it seems to me, is to impart the secret to others. It is with that object I am here to-night, that I have ventured to address you, and to place at your disposal arms of precision that will give you the mastery over disease.

ON TWO CASES BEARING UPON THE QUESTION OF THE LIMITATIONS OF ENTERECTOMY.[1]

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE two cases now to be recorded appear to have some value as, when taken with others, assisting us to form conclusions in regard to the limitations of enterectomy which can only be settled by experience. The first bears upon the question whether this delicate and difficult operation, which demands a very full measure of reparative power on the part of the patient, ought to be undertaken at all in the presence of marked glycosuria. This condition is well known to exercise in various ways a most depressing influence upon all the vital processes and might be assumed for that reason (perhaps too readily) absolutely to contra-indicate an operation, such as the removal of part of the bowel and end-to-end anastomosis of the same. The second, in which five and a half feet of small intestine were removed for gangrene in a woman, aged 76 years, raises the question whether advanced age is of itself a barrier to the removal of large tracts of the intestinal canal with end-to-end anastomosis. It also gives some hints as to the extent to which such excision may be carried and the effects on assimilation of removal of large portions of the small bowel. Both cases having been followed by complete recovery we are in a better position now to argue from experience than before. The first case was as follows.

CASE 1.—A woman, aged 58 years, was admitted into University College Hospital on Oct. 3rd, 1900, under the care of Dr. G. V. Poore. She complained at this time of great pain above the umbilicus and obstinate constipation. She was known to suffer from diabetes and later was found to have 6 6 per cent. of sugar in the urine. The pain had begun eight months ago and the patient was obliged to remain in bed from the middle of May to the end of June, 1900. After this she was advised by her medical attendant, Dr. Baldwin, to go to the seaside for three weeks. Here she improved on a diet chiefly of fish. After returning home the pain was very intense, especially after solid food. She was usually sick from half an hour to an hour after food, but had no hæmatemesis except on one occasion three weeks before her admission into the hospital. Three weeks before she could not keep down even soda-water and milk. She had always been constipated and stated that drugs had no effect upon this condition. Three weeks before admission she had "coffee-ground" vomiting. Her aspect was that of a fairly healthy woman, and in spite of having lost 2 st. 6 lb. in weight during the last six months she looked fairly nourished. She had no appetite. The abdomen on inspection looked like that of a healthy woman who had borne many children (10). There was tenderness above and to the left of the umbilicus, and here an oblong tumour could be felt. It lay across the abdomen and was sausage-shaped and moderately firm and moveable; otherwise the abdominal contents showed nothing abnormal. The urine was acid, its specific gravity was 1040, and it contained no albumin, but it gave the reaction of sugar. When Dr. Poore kindly asked me to see the patient with him we agreed to distend the stomach with air and then after evacuating it to inflate the colon. When the stomach was distended the tumour was a little less evident but was otherwise unaltered. On distending the colon, however, the tumour was pushed to the right iliac fossa and reduced in size. From this we argued that it was probably seated in the transverse colon and was associated with more or less intussusception of a ring-like growth of carcinoma into the distal portion of the bowel. The patient being in a fair condition except for the glycosuria it was determined to attempt removal of the growth. The preparation for operation consisted in clearing out the descending and transverse colon by copious enemata, drugs having failed. Codeine phosphate in one grain doses was given three times daily hypodermically for the diabetes, and 10 grains of carbonate of bismuth three times a day as an intestinal antiseptic.

The abdomen was opened on Oct. 25th, 1900, in the middle line by a three-inch incision, branched below to include the navel, which was excised. The mass was found to the right of this opening, and on being lifted out with ease was seen to be an annular mass of carcinoma, producing a very tight stricture of the colon. The bowel above contained hard scybala and was much hypertrophied; below the mass it was empty, dilated, and thin-walled. There did not appear to be any glandular infection; but there were a considerable number of adhesions with portions of the omentum round the growth. The latter was now separated from the omentum after ligature in several pieces. The bowel was then closed by several pairs of Doyen's forceps above and below the growth, and the middle portion of the colon was cut clean out with scissors, which were also employed to cut across the mesocolon about one and a half inches from the portion removed, in the centre of which was the annular cancerous stricture. The portion of colon removed measured, in the contracted condition, four and a half inches, about one inch of this being taken up by the growth. The ends of the divided bowel were now brought together after being cleansed and were sutured end to end in the usual manner with fine silk stitches in two rows, a deep row and a superficial row. Then the gap in the mesocolon was closed by a continuous silk suture. When the clamps were now removed the continuity of the bowel appeared to be satisfactory, and the abdominal wound was united by silk stitches passing through all the structures of the edges and without any drainage.

The patient bore the difficult and prolonged operation particularly well and soon recovered from the anæsthetic. She expressed herself as at last free from the severe pain from which she had suffered for months. The temperature remained below 100° F. for the first nine days, during which she steadily improved. There was no vomiting except a mouthful soon after the operation. Feeding by the rectum was kept up for four days and small quantities of fluid were given by the mouth from the second day onwards. Morphia was given, at first two or three times daily, but on the third day I began to administer codeine phosphate in doses of one grain hypodermically three times daily on account of the sugar in the urine, which was shown on the fourth day to amount to 6 6 per cent. From this day it steadily declined in amount until on the ninth day it was only 2 per cent. It diminished now still more rapidly when the codeine in the same amount was given by the mouth until the thirteenth day, when it disappeared altogether, only to reappear once to the amount of 2 8 per cent. on the seventeenth day, when it was found that the patient had surreptitiously eaten some sugar and also grapes. After this sugar was either totally absent or only found in a mere trace until the end of convalescence. For the first ten days the original gauze dressings were not removed, as the temperature had remained practically normal and the patient's abdomen appeared perfectly quiet except for some flatulence. On the tenth day, when the dressings were taken off for the first time, it was evident that some suppuration had taken place. The stitches were cutting and the edges were somewhat swollen and red; a few bubbles of gas escaped also with the pus from the upper stitch holes. The temperature, however, was only 99° and the local and general condition otherwise was very good. The wound was supported by American rubber plaster. This day an oil enema was given with only a slight result, but much flatus was passed subsequently. The next morning at the dressing it was quite clear that a small amount of fæces was escaping from the upper stitch holes and this increased for a few days and then began to lessen. After the first two stools on the nineteenth day after operation, which were very copious, the discharge of fæces from the fistula became insignificant until on the twenty-seventh day it ceased altogether for a week. On the thirty-second day there was some swelling and redness at the lower end of the wound, and the next day a slough was seen protruding, which on being pulled on was of about the size of the little finger, and was seen clearly to consist of a piece of omentum or mesentery with one or two silk stitches attached. There had been a smaller slough of the same kind extracted some days earlier, but no record was made of it. All this time the patient's condition was excellent. The bowels acted regularly with or without enemata, and abundant liquid and solid food was taken. Two days after the discharge of the slough above mentioned there was a trace of thin fæces on the dressing, but the wound healed rapidly, and was almost definitely closed on the day the patient left hospital, only a tiny point of granulation remaining. This was on Jan. 13th, 1901.

---

[1] A paper read before the Royal Medical and Chirurgical Society on Feb. 26th, 1901.

The portion of colon removed is four and a half inches long, and shows the hypertrophy of the afferent end and the dilatation and thinning of the lower. In the middle lies the ring of carcinoma, which only admitted the passage of the tip of the little finger before it was slit up. Under the microscope the growth was seen to be an ordinary columnar epithelioma.

The chief interest of this case appears to me to centre round the fact that this patient had for years been a diabetic, and at the time of the operation was getting rid of 6·6 per cent. of sugar in her urine, and was growing thinner. Hitherto such a state of things has generally been held to contra-indicate most severe abdominal operations. But surgery has altered much with the introduction of aseptic conditions, and it is possible that we may consequently have to revise our notions still further in regard to the possibilities of repair in diabetic patients, and with them our practice. Such cases as the foregoing help us somewhat in forming conclusions on this point. Personally, I can only remember three cases in which I have been called upon to do abdominal operations on diabetic patients. The first was one of carcinoma of the rectum with complete obstruction, for which colotomy was necessary. Here there was no repair in the wound and the patient died comatose. The next was a radical cure of an umbilical hernia where the sugar was overlooked before operation. Here, as I expected when the sugar was found, the day after the repair was bad and the wound broke down and only very slowly healed, and although the patient appeared well generally throughout I was very anxious until he left the hospital in good health. In the present case I was, to some extent, encouraged by the last as showing that union of the abdominal wall, at all events, could take place in a diabetic. But there are very few cases, so far as I know, in which enterectomies have been done in this condition, and there was little evidence to show how repair of the gut would take place in a diabetic patient. It appeared, however, probable that if other tissues can heal in the presence of sugar in the blood, the peritoneum, if kept clean, could, with its wonderful reparative power, do so too. I confess I expected more or less of a fæcal fistula in this case. This is very common in enterectomies of the large intestine under ordinary conditions and would be more likely where sugar was present. But in spite of this it appeared proper to face the risks of operation in view of the almost complete obstruction and the inevitable death which must soon follow if nothing was done. The slight sloughing of the omentum and mesentery in this case is new to me. I have tied these structures in many operations, but until now have never seen any evidence of necrosis in them. This, I think, can be fairly ascribed to the lowering of their vitality due to the presence of sugar in the blood.

CASE 2.—The second case was that of a feeble old woman, aged 76 years, who was admitted into University College Hospital on Jan. 10th, 1901. She had always enjoyed good health, *but in 1870 had undergone ovariotomy*. She had had no children. For two years she had had a large ventral hernia in the ovariotomy scar. On Jan. 8th and 9th she had not felt well and complained of some pain in the abdomen, but she was not sick. At 10 A.M. on the 10th she was seized with severe pain in the abdomen and vomited the contents of the stomach slightly bile-stained. The hernial tumour was tender and more swollen than usual. There was no more sickness and no motion or flatus was passed. At 11.20 on that day she was seen by Dr. Rainsford Gill, of King Henry's road, who states in a letter that he was called to see her for what appeared to be a fainting attack. She then appeared in but little distress. Two hours later she had vomited and had another attack of faintness. The vomited matter contained masses of undigested bacon. He again saw her in about an hour, and she "then complained *only* of epigastric pain—*none* in the lump, which she mentioned was as usual. I had," wrote Dr. Gill, "my doubts and sent her down to hospital; the doubt only occurring because manipulation seemed to increase the epigastric pain and I thought it must mean involved omentum." The patient's state on admission was described as follows: "Feeble woman, with intermittent pulse of 108; face pinched; tongue moist; condition, but for age, good. There is a lobulated median ventral hernia five inches in diameter, extending from umbilicus to pubes. The front of the sac has the scar of an ovariotomy in it. The tumour is tense, dull, not tender, and shows no impulse on coughing. There is definite fluctuation and thrill across it." (I should like to say here that the success of the operation was entirely due to this prompt action on the part of Dr. Gill. These cases are hopeless after a certain moment of septic absorption has been reached, and this he forestalled.) When I first saw the patient, at 10 P.M., and examined the mass under an anæsthetic, some of the contents of the sac returned easily and at once and the whole pelvis was found to be full of very hard masses, discovered later, on opening the abdomen, to be fibroids of the uterus probably calcified.

I immediately opened the abdomen through the old scar and about a pint of dirty blood-stained fluid with a fishy odour gushed out. A loop of blackened small intestine was now seen of about three feet in length, strangulated through the omentum. The gut had not entirely lost its lustre, but was very foul and was distended tightly with dark blood stained fluid. The peritoneum was not cracked, but hæmorrhages existed beneath it in several places, and a few of the subperitoneal venules were thrombosed. The extremely foul and fishy odour of the gut and fluid around it determined me to remove it, as its recovery seemed hopeless. I therefore cut away five and a half feet of the bowel and anastomosed end to end as rapidly as possible. The time taken for this part of the operation was 44 minutes, the whole operation to the last stitch requiring 63 minutes. During the operation, which was well borne, 12 ounces of normal saline solution were slowly injected subcutaneously. The whole of the lower part of the abdomen was filled with very hard fibroids of the uterus, which reduced the amount of space for working very much. The surgical registrar's report next morning on the portion of gut removed was as follows: "The parts removed were five and a half feet of small intestine. Three inches from the lower end is the seat of the distal constriction. The gut at this point suddenly becomes intensely congested and hæmorrhagic, of a purple-black colour, and its walls are thickened with intense œdema. At the time of operation there was a definite groove at this spot, which has now disappeared after lying in weak spirit for 12 hours. On tracing the gut upwards from this point the first three feet are all intensely congested, thickened, and œdematous, but the changes become less marked above, and the upper two feet, though now only pale and œdematous, were congested at the time of operation. There is no groove or sudden change in the pathological appearances to mark the seat of any constriction of the proximal loop of gut, the congestion and œdema becoming gradually less when followed up the coil. On slitting up the gut the mucous membrane of the lowest three feet has a deep purple-black colour, and the valvulæ conniventes are so swollen, discoloured, and pulpy-looking that it is difficult to say whether any ulceration exists. After lying some days in weak formalin the parts merely congested became paler and revealed three large patches in the last 18 inches of gut, where the mucosa was hæmorrhagic, partly gangrenous, and superficially eroded. Each patch involved the whole circumference for about three inches, and the lowest one, where the changes were most marked, had a definite, abrupt linear lower border marking the seat of the distal constriction. In the next foot of gut above there were two similar but smaller patches of mucous hæmorrhage and erosion, only involving a part of the circumference of the bowel for about one inch by half an inch."

During the night of Jan. 11th the patient had an enema of hot saline solution with half an ounce of brandy, followed in two hours by a nutrient suppository. She also had one ounce of albumin water every two hours. There was only slight sickness once. The temperature this morning was 100°F.; the pulse was 120, intermitting one in eight; and the respirations were 30. There was slight distension, but no pain or tenderness, and the patient passed urine without the catheter. Her colour was good. There was no flatus. The treatment consisted in nutrient suppositories every four hours, with saline injections per rectum every alternate four hours. She also had one ounce of albumin water with one drachm of brandy every two hours by the mouth. She also took 20 grains of carbonate of bismuth and two minims of solution of strychnia. On this day the temperature rose to 101° but soon fell to below 100°. Fearing trouble in the lungs in an old person I ordered that she should at once be put in a sitting position and kept so throughout, except for a few hours when she was to sleep in the horizontal position.

There is little now to record except uninterrupted convalescence. The food was rapidly increased until soon the patient was taking nine ounces of brandy, 24 ounces of albumin water, eight ounces of Benger's food, and, later, eggs, pounded meat, and fish. My chief anxiety was about the bowels. These acted twice on the fourth day, three times on the fifth day, four times on the sixth day, and five times on the seventh day, which led me to fear septic catarrhal enteritis. This is not to be wondered at when we remember the state of the bowel above the constriction. The diarrhœa was checked, however, by a few doses of solution of opium (five minims) and there was no further trouble until the twelfth day, when there was another looseness of the bowels. There was just a trace of bronchitis, but never enough to cause alarm, and it was kept under by rubbing the back, by adopting the sitting position, and by wool-packing. In order the better to combat all lung trouble I thought it well to let the patient sit up in an arm-chair on the sixth day by the fire for some time. This seemed to produce a good effect. The wound was not dressed until the tenth day, when primary union was found. A strip of collodion gauze was put over the wound and the whole abdomen was supported with rubber plaster.

Returning now to the first of these two cases I need hardly remind this society that important papers have been published comparatively recently in its "Transactions" tending to show that under the improved conditions of antiseptic surgery the prospect of operations for diabetic gangrene are now by no means so gloomy as formerly. But it must not be forgotten that only 35 years ago the Surgical Society of Paris debated the question whether any operations at all ought to be performed on diabetic patients and came to the general conclusion that only those conditions which without an operation would inevitably end in death should be dealt with—as, for instance, by tracheotomy or herniotomy; and many present on that occasion still maintained that no operation, even the smallest, should be done in the presence of glycosuria. But though it has been since shown that amputations for diabetic gangrene have been performed with a fair measure of success we have still but little evidence as to how operations upon the intestines are borne in the presence of glycosuria. This case, then, appears to offer some encouragement,

As far as we know from recent investigation the way in which sugar in the blood and tissues operates in producing that lowering of vitality which finds its grosser expression in gangrene of the extremities and its lesser in more limited necrotic changes in the lungs, intestinal and renal epithelium, is somewhat as follows. The derivatives of altered tissue change due to glycosuria, such as acetone, acetic, lactic, β-oxybutyric, and oxalic acids, injure the tissues and make them more vulnerable to infection. They are the source[9] of occasional necroses of internal organs, of premature angiosclerosis, and, in combination with increased destruction of albumin and diminished repair, are the origin of precocious senility. All recent authors have found extensive arterial disease in diabetes. Degenerative neuritis is a secondary result of this defective blood-supply to the nervous system due to angiosclerosis.

There are, then, two forms of extreme lowering of vitality due to glycosuria, often producing necrosis—(1) that due to angiosclerosis and thrombosis, and (2) that due to inflammatory processes started by virulent forms of bacteria in weakened tissues. Further, it has been shown that the amount of sugar which is found in the blood and tissues of diabetic patients corresponds pretty nearly with the amount which is found by bacteriologists to be most favourable to the growth of pathogenic organisms on cultivation media. Dr. F. W. Pavy pointed out long ago that the blood of diabetic patients contains about on an average from 0·6 per cent. to 0·5 per cent. of sugar, and many experimenters have found that this is the best percentage of sugar for agar-agar or bouillon if the organisms are to grow at their very best, while a higher percentage either inhibits their growth or reduces their virulence. It would follow from this that, after all, the chief danger to wounds in diabetes is sepsis, and that with the avoidance of this even delicate reparative processes, such as the soldering up of intestinal wounds, may be hoped for. The other forms of lowered vitality would remain, of course, as well as that due to chloroform narcosis, and have to be faced. But we can avoid violence to the tissues by delicate manipulation, and can now spare them the further devitalising effects of strong chemical germicides.

The only reference to changes in the intestines found in cases of diabetes made by Dr. R. Saundby, in Allbutt's "System of Medicine," is as follows: "These [the intestines] share in the congestion and catarrh which are found in the stomach; hæmorrhages may be present in the duodenum. The large intestine is generally filled with hardened fæces and occasionally shows dysenteric inflammation or desquamation of its epithelial lining." Again, in his "Summary" Dr. Saundby says: "Diabetes is a disease which has so profound an influence upon the general nutrition of the body that it tends to produce structural alterations in the various organs which are for the most part of a secondary and degenerative character."

Out of the many features of interest in Case 2, that of the removal of five and a half feet of small intestine in a feeble old woman, 76 years of age, for gangrene, I will only specially allude here to three. First, that the advanced age appeared to be no barrier to the most perfect repair, for everything apparently healed as it might have done in a patient 50 years younger. Next, that so far we have no evidence that in her case the withdrawal of so large a part of the secreting surface of the small intestine has had any injurious effect upon the system. Digestion seems now very good and the motions appear normal. Finally, this case suggests that in some cases of internal strangulation with damaged, paralysed bowel, distended with intensely septic products, but not actually gangrenous, it might on the whole involve less risk to cut away all the damaged portion with its contents than to return it to the abdomen with or without evacuation after its release from strangulation. How often have we seen the patients in such cases die from intestinal sepsis or peritonitis many days after the release of a constriction and with a healed wound, the bowel being found after death still flaccid and discoloured, though in no way perforated. Some undoubtedly recover, but often after violent enteritis, and some only to fall victims to other forms of obstruction set up by adhesions.

I may add that just before the first of these cases was admitted to the wards I had to resect in another case 37 inches of small intestine which was all matted together and kinked, causing almost fatal obstruction. In this case I had operated on a strangulated femoral hernia four months before. And though the discoloured loop was far short of gangrene and the usual wound healed perfectly by first intention, admitting of the patient leaving hospital on the sixteenth day, two very severe attacks of acute obstruction, each nearly fatal, followed with intervals of about a month.

---

[9] Grossman: Ueber Gangranes bei Diabetes Mellitus, p. 127.

When in October I opened the abdomen to see the cause the knuckle of intestine which had been in [illegible] hernia was found so sharply kinked and held down by matting adhesions that it was a marvel that the patient had so long survived. Fortunately, the removal of three feet one inch of the damaged intestine with end-to-end union was followed by complete relief, but I now think it would have been better to have done it in the first operation.

APPENDIX.

The consideration of the second of the above cases could hardly be regarded as complete without some references to those other extensive resections of the intestine which have been published up to the present.

Taking one metre (39 5 inches) as a minimum limit I have been able, with the help of various publications (see below), to collect 27 successful resections of intestine exclusive of my own. These range themselves as follows: between one and two metres, 20 cases; between two and three metres, five cases; and between three and four metres, two cases. The amount in this list removed actually ranged between 100 centimetres (3 feet 3½ inches) and 330 centimetres, or 10 feet ½ inch. This largest amount was removed from a boy, aged eight years, whose condition a year later showed no evidence that the loss of so much of his small intestine had unfavourably affected his health. Of the others it can only be said that those who had lost under one and a half metres (4 feet 10¾ inches) appeared to suffer nothing permanently from the operation. Of the seven cases, including my own case, in which between one and a half and two metres had been sacrificed, two showed some disturbance of the assimilative process. My own patient, the old woman, aged 76 years (66 inches = 165 centimetres), has had on three occasions slight diarrhœa to the extent of one or two loose stools, but otherwise appears to be in the best of health and to have put on flesh. In the other (Schlatter's), where 192 centimetres, or 6 feet 4 inches, were removed for strangulation in a healthy man, aged 23 years, the patient was soon able to take any kind of food and increased largely in weight while in hospital. A year after he was found to have lost three kilogrammes and to be unable to undergo prolonged physical exertion. In the five cases in which between two and three metres had been removed diarrhœa is noted in three when the diet was not regulated; otherwise the patients were well. In the fourth case a man, aged 22 years, from whom 202 centimetres of small intestine were removed, there is no record of any intestinal fault; the other was quite well until death two and a half years later. In the two cases in which respectively 310 centimetres and 330 centimetres of small intestine were resected the condition of the patients at the end of a year showed no loss of weight, but in the first, a man, aged 60 years, an analysis of the excreta showed that assimilation was not perfect but was made up for by the amount taken. In only two of all these cases was a careful analysis made of the excreta after the operation. In Fantino's case (310 centimetres) assimilation was obviously below normal. This was indicated by the rapid appearance in the stools of aliments which could be recognised; and besides, the bowels acted more frequently than normal. Moreover, a chemical analysis showed that the motions were richer in nitrogen, fats, and water than normal, but in spite of this the weight increased. In Schlatter's case practically the same results were arrived at by an analysis of the excreta.

From all this it would appear that about two metres of small intestine, say six feet, may be removed without any serious damage to the subsequent assimilative powers. But I think no one can study these cases without arriving at the conclusion that in this length we have probably arrived nearly at the limit of safe resection of the small intestine. And I feel glad that I had some recollection of having read some of these conclusions somewhere when I was suddenly called at night to operate on this case. It led me to roughly measure what I was about to excise by passing it a foot at a time through my fingers before fixing on the spots to divide the bowel. I remembered, I believe, Senn's conclusion that not more than one-third of the whole of the small gut should be taken away; and though the upper part of the bowel at the spot selected for division was still œdematous and hæmorrhagic I determined to keep within these bounds. It is true that Senn's conclusions were based upon his experiments upon dogs, which might be misleading. It is also true, as I have since read, that Trzebecki's experiments on dogs led him to believe that one-half of the small intestine might be safely excised in man, and that Monari, after a series of similar experiments, arrived at the result that dogs will bear the loss of seven-eighths of their small intestine, and that probably the human being might be deprived safely of two-thirds. It is also true that a boy eight years old has actually lived and grown strong after forfeiting 10 feet 10 inches of small intestine. But the danger of arguing from experiments on dogs or from one or two cases affecting the human subject is clearly suggested by some of these cases, which appear to come perilously near the justifiable limit. And the great value of accurate clinical records is thereby to my mind abundantly shown where abstruse physiological problems are involved. It seems probable, from experiment and observation, that in younger patients who survive the operation a compensatory hypertrophy may take place in the small bowel left behind, which may make up for the loss. It seems also to be suggested that the resection is better tolerated the lower down the intestinal tract it is done.

CASES OF RESECTION OF BOWEL TO THE EXTENT OF MORE THAN ONE METRE WHICH WERE SUCCESSFUL.

1. Hahn.—Excised 80 centimetres of small gut and 20 centimetres of large gut in a man, aged 38 years. There was no disturbance of assimilation. The cause of trouble was volvulus.

2. Budberg.—Koch excised 110 centimetres for gangrenous inguinal hernia. The patient, a male, aged 38 years, recovered.

3. Budberg.—Koch excised 107 centimetres of colon for volvulus. The patient was a male, aged 42 years.

4. Troje.—Excised 115 centimetres of small intestine for tuberculous strictures. The patient was a female, aged 25 years.

5. Schlange.—Excised 135 centimetres of ileum for gangrene due to strangulation. There was no disturbance of nutrition. The patient was a female, aged 42 years.

6. Kocher.—Excised 160 centimetres of ileum for gangrenous inguinal hernia. The patient was a male, aged 57 years. There was [illegible] al fistula. [illegible] ere was no [illegible]

[illegible] is not given.

12. Schwalbach.—Excised 183 centimetres of ileum for strangulation. The patient was a female, aged (?) years. The ultimate result is not known.

[illegible] etres of ileum and partly of [illegible] 36 years. There was no dis-[illegible]

[illegible] r gangrene due to mesenteric [illegible] ed 25 years, who was in good health two years later.

15. Roux.—Excised 124 centimetres for a lipoma. The patient recovered.

16. Canthorn.—Excised 109 centimetres for sarcoma of mesentery. The patient was aged 49 years. The patient recovered but died four months later from obstruction by Murphy's button.

17. Maston.—Excised 112 centimetres for sarcoma of the mesentery. The patient recovered, but died five months later from perforation due to Murphy's button.

18. Trombetta.—Excised 110 centimetres. The patient was a female, aged 40 years. She recovered.

19. Barker.—Excised 165 centimetres for gangrene due to strangulation through a hole in the mesentery. The patient was a female, aged 76 years. She recovered, though she had slight diarrhœa at first.

20. Schlatter.—Excised 192 centimetres for gangrene due to wound and prolapse. The patient was aged 23 years. During his stay in hospital he ate *anything and increased in weight. A year after he had* gone back in weight three kilogrammes and could not work as hard as before.

CASES OF RESECTION OF BOWEL TO THE EXTENT OF OVER TWO METRES WHICH WERE SUCCESSFUL. (QUOTED IN PAPERS BY SHEPHERD AND BY DREESMANN.)

1. Kœberle.—205 centimetres of small intestine excised for strictures. The patient was a female, aged 22 years There was no disturbance of assimilation.

2. Kocher.—208 centimetres of small intestine excised for a railway injury. There was diarrhœa when the patient was incautious about his diet. The patient was a male, aged (?) years.

3. Dreesmann.—215 centimetres of ileum excised for gangrene The patient was aged 37 years Diarrhœa was easily produced by errors in diet.

4. Shepherd.—234 centimetres of ileum adherent to tumour excised. The patient was aged 28 years. There were frequent loose stools, but the patient gained 40lb. in weight.

[illegible] tumour 237 centimetres of [illegible] years. For two and a half [illegible] took place from recurrence of tumour.

CASES OF RESECTION OF BOWEL OVER THREE METRES WHICH WERE SUCCESSFUL.

1. Fantino.—310 centimetres of ileum excised for gangrene. The

patient was aged 60 years. There was no emaciation at the end of a year.

2. Ruggi.—330 centimetres of small intestine excised for peritonitis. The patient was a boy, aged eight years, who was quite well a year later.

Note.—Since this paper was written another case has been published by Dr. Blayney of a patient who was operated upon by Mr. Hayes in the Mater Misericordiæ Hospital, Dublin. Here 8 feet 4½ inches (= 251 centimetres) were resected for injury in a boy, aged 10 years. The patient recovered, but is now troubled by looseness of the bowels and occasional vomiting and is losing flesh.

Harley-street, W.

ON HOUR-GLASS STOMACH,

WITH LIST OF SIX CASES OPERATED UPON BY THE WRITER, AND A TABULATED LIST OF ALL CASES IN WHICH OPERATIONS HAVE BEEN PERFORMED.

By B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY; CONSULTING SURGEON TO THE SKIPTON AND DISTRICT HOSPITAL, &c.

HOUR-GLASS STOMACH.

BY "hour-glass" stomach is understood that condition of the stomach in which the viscus is divided into two cavities. The cavities are generally of unequal size. The terms "hour-glass contraction of the stomach," "double stomach," "bilocular stomach" have been adopted by various authors. Hour-glass stomach may be described as "congenital" and "acquired." Congenital hour-glass stomach is commonly asserted to be the more frequent variety. Thus Fenwick writes, "In about 45 per cent. of the cases which have been recorded neither ulcer nor scar could be detected in the stomach, while in the great majority of the cases where an ulcer was present it was obviously of more recent formation than the stricture." And again, "That the deformity is a rare result of ulceration is proved by the fact that only one case of the kind is mentioned in the records of the London Hospital for 40 years, whereas several instances of the congenital form of the disease were encountered during the same period of time." Similar statements have been made by Carrington, Roger Williams, Hirsch, and, in fact, every writer who has dealt with the subject.

Now, I have examined carefully many museum specimens, I have operated upon six cases personally, and I have seen others in the practice of my friend Mr. Mayo Robson, and I say deliberately that the evidence of the existence of hour-glass stomach as a congenital deformity is insufficient to be convincing. I do not deny that congenital cases may exist, for, as a fact, they are not improbable when we contemplate the circumstances in congenital stenosis of the pylorus; but I am sceptical that any of the recorded cases of congenital deformity are in reality of such an origin. It is a noteworthy fact that in many of the so-called congenital cases, if not in all, ulceration was present in some part of the stomach. This is true of Carrington's cases, of Hudson's, Saundby's, Williams's, Saake's, and Hirsch's. In Watson's first case it is said that the mucous membrane at the point of constriction and on each side of it "is thrown into abnormally heavy ridges," which implies that a process of narrowing from a larger bulk has here occurred. In certain of the museum specimens labeled "congenital" it is quite clear that no adequate examination of the specimen has ever been made. Indeed, such an examination necessitates a so free handling of the specimen as to spoil it almost entirely for decorative purposes. The simple aspect of a pathological constriction can be most deceptive. Case 5 related below was an exemplary instance of this. The isthmus uniting the cardiac and pyloric cavities was barely the size of one's little finger; it was perfectly soft, smooth, and everywhere supple. There was no trace of any thickening or puckering of the surface. On invaginating a finger into the cavity on each side of the narrowing no orifice could be felt leading from one to the other. To all appearance no pathological process had ever existed there. On slitting the stricture up, as a preliminary to performing gastroplasty, I found the following condition. The passage was equal in diameter to a No. 4 or No. 5 catheter; most of its circumference was natural in appearance, but at the upper and anterior part was a small dead-white area, tough and clearly cicatricial, and from near this there ran, on the pyloric side vertically down to the opposing mucous surface, a column clad completely in mucous membrane and half-an-inch in diameter. I removed this column between two ligatures and it was then found to be built up of dense fibrous tissue. There was, in fact, a "bridle stricture" in the stomach. That it was pathological admits of no question, yet nothing short of a division of the stricture could have revealed its inflammatory origin. I have no doubt that if the whole stomach had been obtained from a post-mortem examination the specimen would have been proclaimed to be an admirable example of congenital hour-glass stomach.

Hochenegg on a similar case performed the operation of gastro-gastrostomy. No careful examination of the narrow stricture was made, but the case is quoted as an example of "congenital" deformity. Such a case is quite inadmissible. Doyen's case, referred to in the list, is christened "congenital." At the point of narrowing there was an ulcer adherent to the anterior abdominal wall. On separating the adhesions a gastric fistula was exposed showing unmistakeably that a localised perforation of the ulcer with anchoring was responsible for the warping of the stomach.

Williams[1] describes 10 cases of "congenital contraction of the stomach." The account of one of the cases is based on the examination of a wax model, of another on the inspection of an "inflated dried" specimen, and a third on the appearance of a "dried stuffed" specimen. It is doubtful whether one of the examples can be accepted as an "hour-glass" stomach. In all the rest pathological conditions, ulceration, puckering, thickening, and adhesion to pancreas were present. It is improbable that any one of the stomachs was the seat of a congenital deformity. The same criticism applies to Carrington's cases and to Maier's. The facts that pathological changes producing marked changes in the contour of the stomach may be inconspicuous, that ulceration in association with "congenital" deformity is frequent, and that in many of the examples no purposeful examination of the specimen has been made, warrant me in saying that congenital hour-glass stomach is certainly rare and not improbably mythical. In 20 examples of this supposed variety collected by Watson the stricture was situate in the middle in seven, at the junction of the upper and middle thirds in three, at the junction of the lower and middle thirds in four, and was not noted in six.

ACQUIRED HOUR-GLASS STOMACH.

Acquired hour-glass stomach may be caused by (1) perigastric adhesions; (2) ulcer with local perforation and anchoring to the anterior abdominal wall; (3) circular ulcer, with subsequent cicatricial contraction and induration; and (4) cancer.

1. *Perigastric adhesions.*—These may be the result of many causes; among them being perforation of a gastric ulcer. The adhesion chiefly concerned in producing the condition may be a thick cord running downwards from the liver and sharply pressing into the anterior wall of the stomach. In one of Mr. Mayo Robson's cases such an adhesion caused the cardiac end of an hour-glass stomach to be itself divided into two, thus forming a "trifid stomach."

2. *Ulcer with local perforation and anchoring of the stomach to the anterior abdominal wall.*—In this form a chronic ulcer of the anterior wall of the stomach makes its way in languid fashion through the coats of the organ. As it nears the serous coat adhesions are formed, binding it to the parietal peritoneum, which solders the base and prevents a general leakage. The stomach being then firmly anchored at this one point a sagging of the cavity on each side, but chiefly in the cardiac side, occurs, and this, with the cicatricial contraction occurring in the ulcer, results in an hour-glass stomach. An excellent example of this is Case 1, referred to below. Similar cases are recorded by Steffan and Finney.

---

[1] Journal of Anatomy and Physiology, 1883.

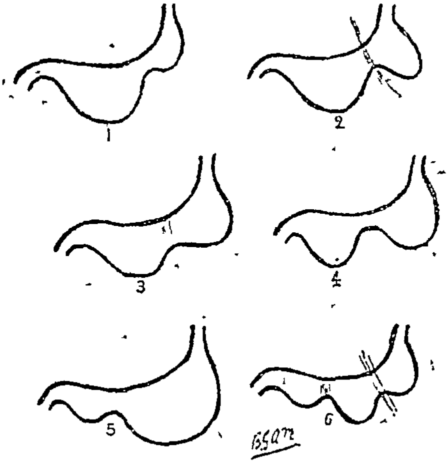
3. *Circular ulcer, with subsequent cicatricial contraction and induration.*—Such an ulcer extends transversely to the long axis of the stomach, and in its contraction while healing must inevitably cause a high degree of narrowing. The simple round ulcer is also fully competent to produce a stricture, though probably not with the same completeness as the former. The conditions found in one at least of my cases, Case 4, suggest very forcibly the likelihood of the ulcer having perforated into the general peritoneal cavity. The scar of the ulcer reached the serous coat, a tough cord-like adhesion sprang from its very middle and extended upward to the liver, while all around were extensive adhesions of varying degrees of toughness. The stricture formed in this manner may be placed at any part of the stomach; it is generally near to the middle, or rather to the pyloric side of the middle. The calibre of the orifice may vary from that of a No. 4 or No. 5 catheter to that sufficient to allow of the passage of three fingers. The greater curvature is generally puckered up towards the lesser, but the reverse is recorded in one case by Schwarz. Perforation of the ulcer at the constriction may occur, as in a case recorded by Siewers.

4. *Cancer.*—Cancer of the stomach is a not infrequent cause of hour-glass stomach. In some of the specimens the cancer has clearly been implanted upon a chronic ulcer—"ulcus carcinomatosum." In others the cancer, originating in a localised area of the stomach and there producing the constriction of the hour-glass, has in its later growth involved the greater part, or even the whole, of the stomach. The stomach then is thickened in all its coats by a diffuse growth and the condition described as "leather bottle" stomach results. This latter state was well seen in Case 6 of my list, in which jejunostomy was the operation of necessity.

SYMPTOMS.

The symptoms of hour-glass stomach are most often those of dilated stomach supervening upon chronic ulcer of the stomach. In most of the cases recorded a diagnosis of "dilated stomach" has been made, and in those dealt with surgically operative interference has been undertaken for the relief of supposed pyloric stenosis. In certain cases, however, the symptoms and signs are clear and pointedly characteristic. In Case 4 and Case 6 of my list a confident diagnosis was made thereon. Two of the most helpful signs were pointed out by Wölfler. They are as follows: 1. A phenomenon observed upon washing out the stomach. The fluid introduced into the stomach seems to disappear altogether "as though it had flowed through a large hole," and is not returned through the tube. In such a circumstance the fluid passes, it is obvious, from the one compartment to the other. 2. It was further noticed that when the stomach was washed out until the lotion returned clear a sudden, unlooked-for gush of foul or even putrid fluid occurred; or, if, after gentle lavage until the stomach seemed clean, an interval of a few minutes was allowed to elapse and the tube again passed, foul or dirty fluid at once returned. This is due, doubtless, to the reflux of the contents of the pyloric cavity through the stricture. Jaworski[2] noticed in one instance that after apparently emptying the stomach by passing the tube a splashing sound could still be obtained by palpation over the gastric area The pyloric cavity, which is not drained by the stomach-tube, causes this suggestion of dilated stomach. The condition has been aptly described as "paradoxical dilatation." Eiselsberg remarked in one of his cases that upon injecting a quantity of fluid into the stomach there were a bulging and distension of the left side of the epigastrium; after a few moments this gradually sank and subsided and simultaneously a swelling of the right side of the epigastrium slowly developed. A sign to which Eiselsberg also called attention in this case was well exhibited in Case 4 in my list On distending the stomach with CO_2 the bubbling and gushing of fluid through a narrow chink could be heard with the stethoscope, an observation that was repeated in Watson Cheyne's case. Case 4 also showed a sign the existence and the value of which I have not seen emphasised before. On examining the abdomen I carefully percussed out the limits of the stomach. After distending with CO_2 the area of tympany, previously marked out upon the lower part and side of the chest wall in front, was more than doubled in size. At the same time a small distended stomach, as it seemed, occupied the epigastrium and a narrowing to its left was clearly seen. Auscultation over this narrowing revealed the sign above mentioned. As the limits of the epigastric swelling were sharply defined and unmistakeable and as there was a doubling of the subcostal tympany, there was clearly a constriction between the two inflated cavities and this constriction must be the isthmus of an hour-glass stomach. Investigation in this manner would have revealed this sign very clearly in Pollard's case and in Childe's case recorded in the list There can be no risk in distending the stomach with CO_2 and therefore this method should be adopted in all doubtful cases. It seems not unlikely that the sign will be most helpful in making an accurate diagnosis. In two cases seen by Schmidt-Monard and Eichhorst a distinct sulcus separating two dilated cavities was seen on inflation with CO_2

The symptoms resulting from a narrowing in the stomach will naturally depend upon the part of the viscus affected. If the contraction be near the pylorus the cardiac pouch will distend to almost any capacity and the clinical picture will be that of dilatation of the stomach. If the stricture be placed but a little way from the cardia the symptoms will suggest œsophageal obstruction. The differential diagnosis can, however, be achieved by noting the distance which the œsophageal bougie passes. In Case 6, seen with Dr. J. Sykes of Cleckheaton, a correct diagnosis was made and a seemingly accurate estimate of the capacity of the cardiac pouch was formed by observing the following symptoms. When the patient took a tablespoonful of milk he retained it; if an ounce or two were drunk at a gulp the greater part was returned. The stomach-tube passed 18 inches without difficulty. On attempting to wash the stomach out one ounce or a little more of fluid passed in, but no more. We administered a seidlitz powder in separate halves. The first half was retained; on administering the second the patient was overwhelmed by a gush of foam which burst from his mouth and nostrils The diagnosis of hour glass stomach, with a smaller cardiac and a larger pyloric segment, was made. At the operation this condition was found; it was the result of malignant disease which had already caused secondary deposits in the parietal peritoneum and ascites.



T [illegible] tion. 4. A narrow channel connects the two pouches. 5. Constriction near the pylorus; simulates pyloric obstruction. 6. Hour-glass stomach; the cardiac complement subdivided by an adhesion, "trifid stomach"

The characteristic signs which may, singly or in association, be present, then, are: (1) disappearance of fluid introduced through the stomach-tube, "as though it had flowed through a hole" (Wölfler); (2) after cleansing of the stomach by lavage a sudden gush of putrid, sour, ill-digested food, &c.

31	Sidney Martin and Bilton Pollard, 1900.	Hour-glass contraction and stenosis of pylorus. At the first constriction there was a small perigastric abscess. The second compartment was much larger than the first. Pylorus very stenosed and peripyloric abscess found, due to perforating ulcer just beyond pylorus.	Gastro-jejunostomy. The second compartment of the stomach united to the intestine.	Death on fifth day.	Brit. Med. Jour., vol ii, 1900.
32	Childe, 1901.	Hour-glass stomach. The cardiac portion lay under cover of the ribs and was not noticed until the necropsy. The pyloric portion was supposed to be the whole stomach and "was not abnormally large."	Gastro-enterostomy, between pyloric segment and jejunum.	Death on fifth day.	Ditto, 1901.

This list includes all published cases with the exception of Mr. Mayo Robson's, which will be reported shortly.

PERSONAL CASES DEALT WITH BY OPERATION.

No.	Date.	Sex.	Age: years.	Symptoms and description.	Condition found; operation.	Result.	Remarks.
1	August, 1899.	F.	39	Ten years ago the patient had an illness characterised by profound anæmia. Seven months ago there were clear symptoms of ulcer of the stomach, but neither then nor at any time any acute illness suggestive of perforation. Now vomited after all ordinary food, and more often than not even after small quantities of fluid food. Pain after food was exceedingly severe. On examination of abdomen a dilated stomach could be felt At one point, a little to the left of the middle line and slightly below the ensiform cartilage, was an area two inches in diameter which was markedly tender and offered increased resistance on palpation. This area was found at the operation [illegible] last few months.	H[illegible] stomach, the narrow con[illegible] side of this the stomach dilated and seemed to be anchored by the adhesion. On separating the stomach from the abdominal wall an opening into the viscus was exposed and the stomach contents escaped. This opening was enlarged transversely and the wound and fistula were stitched up vertically. An omental graft was brought to cover in the sutured area in order to guard against future anchoring.	Recovery.	For a month after the operation there were pain at times and loss of appetite. Since then she has been free from pain and in excellent health. Appetite and digestion are good. Patient seen with Mr. Bailey, Horsforth.
2	April, 1900.	F	27	There was no history of gastric ulcer. The patient had complained of irregular attacks of pain in the epigastric region for 11 months, always associated with the taking of food, [illegible] splashy; contractions were seen when distended. Medical treatment had proved unavailing.	Hour-glass stomach. The constriction was about four inches from the pylorus; the passage between the two sacs equalled a No. 12 catheter in diameter. There were marked induration and puckering, but no adhesion to the abdominal wall or elsewhere. The strictured neck was divided by an incision about two and a half inches long in the transverse direction and stitched up vertically, the mucous membrane with a continuous cat-gut suture and the serous with a continuous silk suture. Two additional interrupted sutures were applied at each end of the wound.	Recovery.	Vomiting for five days after the operation, blood-stained. Since then perfectly well. Patient seen with Dr. Waugh, Skipton.

PERSONAL CASES DEALT WITH BY OPERATION (*Continued.*)

No.	Date.	Sex.	Age: years.	Symptoms and description.	Condition found; operation.	Result.	Remarks.
3	Jan. 24th, 1901. Hospital, Registered No. 443	M.	45	Ailing for three years. Pain in the epigastrium radiating to the left chest. Was worse after food, coming on "within half an hour" and lasting for from two to four hours unless relieved by vomiting. Frequently vomited about an hour after food; never any blood. Lately the pain had been almost constant, aggravated by food, and eased by vomiting. Had lost 2st. 12lb. Dilated stomach. On distending with CO_2 a notch was noticed at the upper border of the stomach and a tentative diagnosis of hour-glass stomach was made. Free HCl. A trace of lactic acid and a few rod-shaped bacilli.	An hour-glass stomach. The scar of the ulcer was equal in size to a florin, was situated close to the lesser curvature and nearer the cardiac orifice than the pyloric. There were much puckering and induration of the surface. There were no adhesions. The index finger entered but could not pass the stricture. An incision three and a half inches long was made transversely and stitched longitudinally in two layers. A slender adhesion of gall-bladder to the pylorus was divided. (Gastroplasty, gastrolysis)	Recovery. Before leaving hospital the ordinary diet without any discomfort.	Weight before operation, 8st. 6lb. Patient seen with Dr. Trevor Pritchard, Retford.
4	March 6th, 1901. Infirmary, Registered No. 1221.	F.	23	Symptoms of gastric ulcer for more than five years. Was under treatment at beginning of illness at the infirmary. Had been gradually getting worse. Vomited now after every meal; pain and vomiting came on about from half an hour to one hour after food. Vomit was very "sour." On examination, hour glass stomach. On distending with CO_2 the cardiac half increased considerably, forming a very large lymphatic area. The pyloric half distended but little; the division was clearly seen. On auscultation a forcing, gurgling sound was distinctly heard.	Hour-glass stomach. The cardiac side of constriction was much dilated and larger than a normal stomach. Rather beyond the middle of the organ was a constriction that would just admit the forefinger; round constriction were much induration and many adhesions; especially noticeable was one thick cord-like one coming from the liver. This was divided between ligatures. The liver was slightly torn on separating widespread adhesions along the lesser curvature. Below it on each side the stomach sagged and between the cavities an anastomosis was made which readily admitted three fingers. (Gastro-gastrostomy, gastrolysis.)	Recovery.	Patient seen with Dr. Waugh, Skipton.
5	March 9th, 1901. Infirmary, Registered No. 1237.	M.	55	Stomach troubles for 16 years. At first pain after food and occasional vomiting. Five years ago an acute attack of hæmatemesis, melæna, and general swelling of the body, which it was feared might prove fatal (? perforation). No ease in the stomach since then; constant vomiting, pain after every meal, and great wasting. Now looked thin, pinched, and shrivelled. For three weeks had had no food, only sips of water and nutrient enemata. On examination, dilated stomach. Free HCl.	Hour glass stomach At first it was thought to be a dilated stomach; on tracing the stomach towards the pylorus an extremely narrowed isthmus (barely as thick as the little finger) was come to which was supposed to be narrowed pylorus, but on tracing beyond it stomach was still found. On invaginating a finger from each side of constriction no opening could be felt. Many adhesions were separated until all was clear and free. Then incision into the stomach or cardiac side of the isthmus and a probe-director was passed through constriction, which it fitted snugly, the opening being no bigger than a No. 4 or No. 5 catheter Gastroplasty was performed. On the pyloric side of the stricture was a column of mucous membrane forming a bridle stricture. This was ligatured, divided at both ends, and removed.	Recovery.	Patient seen with Dr. Mackay, Knaresborough.
6	March 3rd, 1901.	M	54	Vomiting of fluid if taken in quantities exceeding an ounce (see text).	Hour-glass stomach. Narrowing close to cardia due to malignant disease which had invaded the stomach everywhere. (Jejunostomy.)	Recovery (operation, March 12th).	Patient seen with Dr. Sykes, Cleckheaton. Is not making any material improvement.

(Wolfler); (3) "paradoxical dilatation," succussion splash in pyloric cavity after syphonage of the cardiac loculus (Jaworski); (4) distension of cardiac loculus, its gradual subsidence, and concomitantly the distension of the pyloric loculus (Eiselsberg); (5) during this period a gurgling, forcing sound heard over, or near, the middle of the stomach (Eiselsberg); (6) on distension with CO_2 a large increase even to a doubling in the thoracic area tympanitic on percussion and a slight distension, clearly demarcated, of the pyloric loculus (Moynihan); and (7) rarely a sulcus may be seen on inflating with CO_2 (Schmidt-Monard).

TREATMENT.

The following operations have been practised in cases of hour-glass stomach: (1) gastroplasty, with or without resection of the ulcer; (2) gastro-gastrostomy or gastro-anastomosis; (3) gastro enterostomy; and (4) partial gastrectomy. Frequently, owing to the existence of adhesions, gastrolysis has to be performed in addition to the operations mentioned.

The choice of an operation will be determined by the conditions found at the operation. It is essential that a careful and complete examination of the whole stomach should be made before any procedure is adopted. For in some of the cases related below it will be noticed that the lack of adequate and precise knowledge has led to futile measures and fatal results. If the constriction be near the middle of the stomach, if there be little induration and no active ulceration, and if the pylorus be free, a gastroplasty will prove successful. If the constriction be in any part of the middle third or half of the stomach, if the pouches on each side are "sagging" and free from adhesion, and if the pylorus is free, a gastro-gastrostomy will suffice to effect a cure. If, however, the stomach narrowing be associated with pyloric stenosis, the existence of which must be suspected if the pyloric segment is dilated also, no single operation will suffice. A gastroplasty and a pyloroplasty, or a gastroplasty and a posterior gastro-jejunostomy must both be performed. It is possible that in some cases, such as that of Schwarz, where the lesser curvature is dragged down to the greater, that the incision dividing the constriction in the stomach might be utilised for the purposes of an anterior gastro-jejunostomy. If on separating parietal adhesions a gastric fistula be found as in Doyen's case and in Case 1 of my list, the ulcer may be excised, or its edges may be trimmed, and a gastroplasty may be performed. If the constriction be due to new growth, a partial or complete gastrectomy may be performed. If these prove not feasible, a palliative jejunostomy may be necessary, as in Case 6.

Various operators have expressed individual preference for certain methods Thus Eiselsberg, whose experience has been extensive, prefers gastro enterostomy He has performed 11 operations upon eight patients; three of the patients died as a result of the operation, and of the five survivors one suffered from a recurrence of the symptoms at the end of nine months Eiselsberg objects to gastroplasty, that recurrence of the stenosis is probable The same objection has been brought by Berg and others against pyloroplasty The probability is that while the process of ulceration is still active it is unwise to perform a gastroplasty or a pyloroplasty, but that when the healing is complete, when perigastritis is absent, and the incision through the stricture is of good length, no relapse need be feared It is especially important to observe the condition of the pyloric portion of the stomach If the isthmus be a narrow one the pyloric segment should be small and empty. If the pyloric cavity be dilated, as is expressly noted in Jaboulay's case and in Watson Cheyne s, there is a strong presumption in favour of the existence of a pyloric narrowing If such narrowing be present and a gastroplasty alone be *performed, the operation, though "succes•ful" so far as* recovery is concerned, cannot be expected to relieve the patient of all disabilities, and a second operation may be imperative

1 *Gastroplasty* —This is an adaptation to the body of the stomach of Heineke's operation for pyloric stenosis It was performed by Bardeleben in 1889, by Kruckenberg in 1892, and later by Zeller and Doyen A transverse incision, four inches in length at least, is made, dividing the stricture The incision is then stitched up vertically Two continuous layers of sutures are introduced, one for the mucous membrane only, or all the coats, and the other for the serous and sub serous coats alone

2 *Gastro gastrostomy or gastro anastomosis* —This was first performed by Wölfler in 1894 The incisions made into the dependent *pouches on each side of the constriction* were vertical and seven centimetres in length An adequate anastomosis between the two halves was thus made Sedgwick Watson in 1895 successfully performed gastro anastomosis in a different manner The incision in the two segments of the stomach were transverse The pyloric portion of the viscus was folded over the cardiac, with the constricting isthmus as a hinge, and the two were stitched together with an elliptical line of sutures before being opened The anastomosis was then made by incising the wall of the pyloric compartment which now lay anterior and through the opposite surface, making the anastomosis This method is unnecessarily cumbersome and possesses no potential advantages over Wolfler's method,

3 *Gastro-enterostomy* —If the anastomosis is made between the pyloric cavity and the intestine the operation must obviously be ineffective, as the constriction is not relieved If between the cardiac cavity and the intestine the pyloric loculus will be undrained and a second operation, as in Tuffier s case, may be necessary

4 *Partial gastrectomy* —In cases of cancer always, and in certain cases of simple disease, a partial gastrectomy may be the operation of choice In cancer a wide excision should be made, in simple disease a removal of the constriction will suffice In both an end to-end suture is desirable

Leeds.

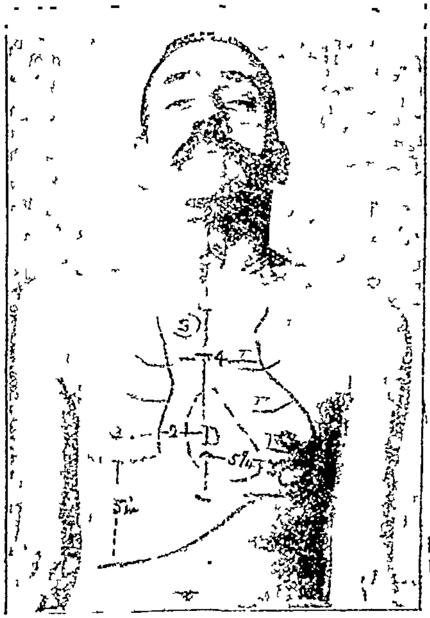
REVERSED PULSUS PARADOXUS DUE TO ANEURYSM OF THE AORTIC ARCH

BY JOHN HAY, M B, CH B VICT, M R C S ENG, L R C P LOND,
MEDICAL REGISTRAR AND TUTOR, LIVERPOOL ROYAL INFIRMARY LATE ASSISTANT MEDICAL OFFICER, MILL-ROAD INFIRMARY LIVERPOOL.

RESPIRATORY variations in the radial pulse due to aneurysm must be of comparative rarity, as I can find no mention of such a condition in the works of Sansom, Gibson, Fagge, Osler, Pepper, and others These authors all describe variations from the normal in the radial pulse as a frequent accompaniment of aneurysm and they emphasise the importance of these variations as aids in the localisation of the aneurysm The variations are (1) complete absence of one radial pulse; (2) inequality of the two radial pulses in volume as felt by the fingers, (3) difference in the character of the sphygmograms; and (4) delay in pulse at one or other wrist They are caused by a number of conditions (1) disease at the mouth of a vessel rising from the arch, (2) deposit of fibrin producing narrowing or occlusion of a vessel, (3) aneurysmal dilatation of a vessel, (4) pressure on a vessel by an aneurysm, or (5) involvement of a vessel on the sac of an aneurysm The case which I am recording, however, presented the interesting feature of a rhythmical variation in the right radial and right carotid pulses coincident with respiration and was due to the innominate artery being compressed between the aneurysm behind and the sternum and costal cartilages in front, the lumen of the artery being almost occluded towards the end of expiration

The patient, a man, died in February, 1900, at the age of 36 years Until the early part of 1897 he had been in good health, but at that time he began to suffer from difficulty in breathing This became worse, and he was admitted as an in patient to the Liverpool Royal Infirmary, and since then, up to the time of his death, he was constantly a patient in one or other of the Liverpool hospitals He had worked as a stoker on board steamers and as is so often the case with that class, he drank large quantities of fluid, *chiefly water, indulging also in beer and stout In 1886* he had a slight attack of rheumatism and in 1889 he contracted syphilis When in India and Brazil he also suffered from malaria Thus we have as etiological factors—syphilis, strain, excess in fluids, malaria, and possibly rheumatism He complained of pain all over the back and chest when he coughed This pain was most severe between the shoulders, especially to the left of the middle line, and tenderness was present over the same area He also suffered from constant headache, and a heavy dizzy feeling He had frequently the sensation of being suffocated, and he could not lie down with comfort but had to be propped up in bed Swallowing anything solid was painful

FIG 1

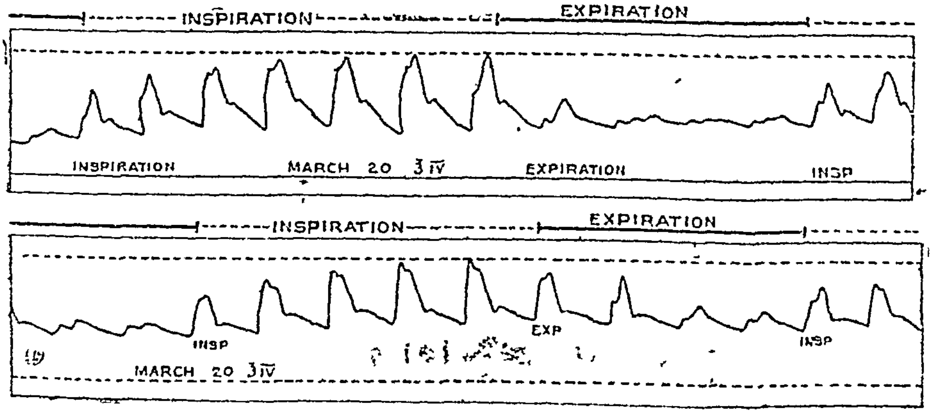


Shows (1) area of heart and aorta as mapped out on chest (2) larynx pushed to the right of the middle line by the aneurysm, and (3) distended veins of the arms S site of maximum intensity of the systolic murmur, situated over the origin of the innominate artery D site of area of the faint diastolic murmur

On examination it was noticed that the trachea and larynx lay more to the right than normal and that with each beat of the heart they made an excursion still further to the right Associated with this condition, and perhaps partly due to it, there was a fulness of the right side of the neck. The veins of the arms were engorged and prominent. The manubrium and inner end of the left clavicle were both observed to move forward with the systole of the heart and on palpating in the suprasternal notch or behind the left clavicle a most distinct expansile pulsation was felt. Tracheal tugging was present. He was much troubled by a cough, bass and deep but wheezy and non-explosive. Examination of the larynx revealed that his left vocal cord was shortened, white, and motionless. The left pupil was smaller than the right. The area of cardiac dulness was much larger than normal. At the level of the second costal cartilage the transverse dulness measured four inches. The illustration shows the limit of cardiac and aortic dulness as mapped out with a pleximeter. The photograph was taken after marking out the area on the chest with Indian ink, so that we have an exact representation of the actual condition (Fig. 1).

Two murmurs were audible. One was a systolic murmur which was loudest over the first right cartilage at the area marked S. It was rough and short and it varied with respiration and was conducted up into the neck, more especially so on the right side. The other, a diastolic murmur, could not be heard over the right second intercostal space, but it commenced at the level of the third costal cartilage, D, and was loudest over the lower end of the sternum. It was conducted towards the axilla and was a faint, blowing murmur not influenced by respiration. On auscultating between the scapulæ a short systolic murmur was audible, conducted almost down to the lumbar vertebræ. No pulse could be felt in the left carotid, axillary, or radial arteries, whilst the pulse in the right radial and carotid arteries varied in the most peculiar manner with respiration. The radial pulse was rather water-hammer in character. Air did not appear to enter the left side of the chest as freely as it did the right, the expansion, breath-sounds, vocal fremitus, and vocal resonance all being less marked over the left than over the right side. The percussion note was not impaired. The patient expectorated a fair amount of mucus which occasionally contained blood. The specific gravity of the urine was 1018 and there was no albumin. Such is briefly the outline of the case and from it was gathered the presence of an aneurysmal dilatation of the arch of the aorta pushing the trachea to the right and slightly diminishing the calibre of the œsophagus. There was also regurgitation through the aortic orifice.

FIG. 2.



Pulse tracing of right radial.

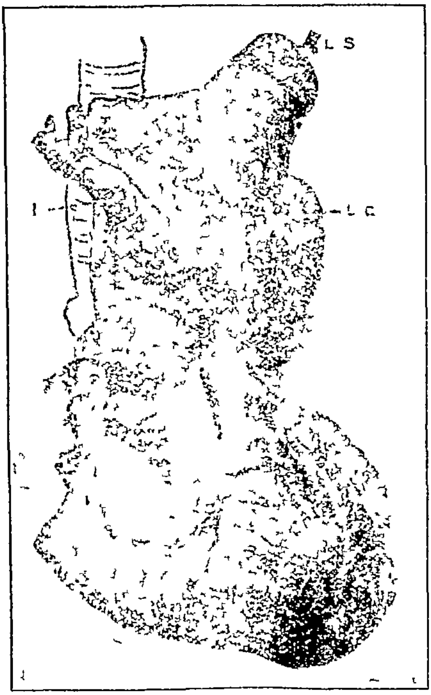
The interesting feature in the case, however, was the effect of respiration on the pulse in the right radial and carotid arteries. The two tracings which are reproduced are from the right radial artery and have the following points of interest: (1) a marked diminution of the volume of the pulse with expiration; and (2) the presence of a definite anacrotic wave the position of which in the upstroke of the tracing varies with the respiratory variation (Fig. 2). It was noticed that during expiration, especially if the act were exaggerated, the radial pulse at the right wrist disappeared. This condition existed also in the right carotid artery, but there was no evidence of respiratory variation in a pulse tracing from the anterior tibial artery. It was also observed that this phenomenon was only present when the patient was in certain positions, it being most marked when he sat up and turned to the left. It was also present when he lay semi-recumbent and leaning to the left. Turning over to the right side, especially when semi-recumbent, did away with the variation and the pulse became regular. Another most interesting fact was noted which considerably assisted in an accurate diagnosis—namely, that the systolic murmur, which, as we have seen, had its area of greatest intensity over the site of the origin of the innominate artery, also varied in intensity with the respiratory movements, becoming much louder and harsher during expiration and diminishing during inspiration. When the right radial pulse was small or almost imperceptible the systolic murmur was loudest and harsh. As the pulse regained its volume and force the murmur lost in audibility and roughness. The diastolic murmur, on the other hand, did not change, but was constant in character and intensity.

One of the most common causes of well-marked anacrotism is aortic stenosis, and it is also recognised that stenosis produced either naturally or artificially in any artery may give rise to an anacrotic pulse beyond the constriction. Here we have an anacrotic wave which varies in position in the up stroke of the tracing, at one time being almost on the base line, while a few beats further it is seen reaching almost to the top limit of the tracing. Note that this variation in the position of the anacrotic wave is regular. On examining a number of tracings the anacrotic wave could be seen ascending higher with each pulsation, reaching its limit and then descending more or less regularly towards the base line.

One of the tracings reproduced shows a variation from a slight anacrotic curve on the base line to a record which gives no anacrotic wave at all. The inference made from this was that in this case the position of the anacrotic wave indicated the extent of the stenosis. With marked obstruction the wave approached the base line and with slight obstruction the summit of the tracing. We had, therefore, three conditions varying with respiration: (1) pulse volume; (2) position of anacrotic wave; and (3) systolic murmur over the origin of the innominate artery. This rhythmical variation in the pulse was therefore considered to be due to "a mechanical cause, probably some kinking of the innominate artery during expiration, as the chest wall descended." The first and second of these conditions suggested the existence of some stenosis which varied with respiration, and the fact that this reversed pulsus paradoxus was present in both the right carotid and the radial arteries together with the third condition pointed to the origin of the innominate artery as the spot where the obstruction to the blood-flow took place.

The post-mortem examination, at which, through the courtesy of Dr. J. Lloyd Roberts, I was present, cleared up the case. It was found that there was considerable dilatation of the whole arch of the aorta, more especially of the transverse portion (Fig 3). The aneurysmal dilatation extended upwards rather irregularly, one rounded projection having crept up and become tightly adherent to the anterior surface of the trachea. In the production of the dilatation it was chiefly the posterior portion of the aorta in the region of the transverse arch which had distended, the result being that the innominate and left carotid arteries, instead of arising from the convexity of the arch, as is usually the case sprang from its anterior surface, and consequently as the sternum and bony thoracic wall descended with expiration these two arteries were caught and compressed between the thoracic wall in front and the aneurysm behind The result of this pressure on the left carotid artery had flattened it down on to the aneurysm and had obliterated its lumen When the patient leaned to the right his heart and aorta would be slightly displaced in that direction and so the innominate artery was freed from compression Thus was caused the increasing and decreasing obstruction in the innominate artery which gave rise to the rhythmical variation in the pulse The aorta was much dilated as far as the lower border of the seventh dorsal vertebra, the bodies of the fifth, sixth, and seventh vertebræ being deeply eroded The œsophagus was compressed by the dilated aorta The valves of the heart were normal with the exception of the aortic cusps which were somewhat fibroid and allowed of free regurgitation The heart itself was considerably hypertrophied and dilated

FIG 3



Photograph of the heart and aneurysm of the aorta, seen from the front. I. Innominate artery rising from the anterior portion of the aneurysm L S., Shrivelled left subclavian artery L C, Shrivelled left carotid which was flattened down and adherent to the front of the aneurysm.

In conclusion, I desire to express my indebtedness to Dr Nathan Raw for permission to publish this case

Liverpool

HEALTH OF BATH – Dr W H Symons, the medical officer of health of Bath reports that 933 deaths were registered in Bath during 1900, which is equal to a crude death rate of 17 72 per 1000 Excluding the deaths of persons who had been brought to Bath for treatment at the public institutions, the corrected death rate corresponded to 15 24 per 1000 compared with 15 83 in 1899 The zymotic death rate was 0 70 per 1000 The number of deaths under one year of age was 121 which is equivalent to an infantile mortality of 126 per 1000 births

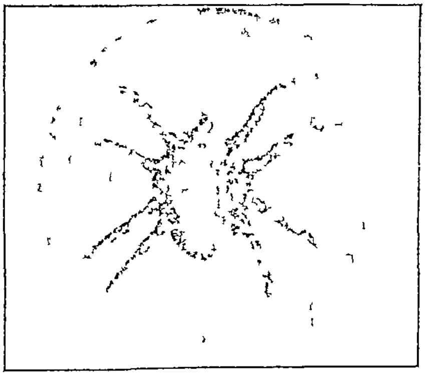
CASE OF A PARASITE—"ARGAS (OR ORNITHODORUS) MÉGNINI" (DUGÈS)—IN EACH EAR

BY J CHRISTIAN SIMPSON, M D EDIN

[WITH A NOTE ON THE ANATOMY OF THE SPECIMEN BY E G WHELER]

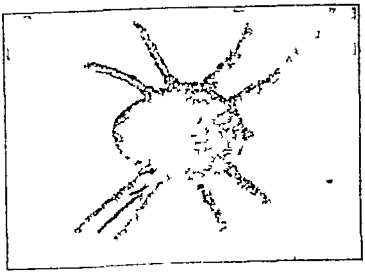
ON August 26th, 1900, Professor —— brought me a living specimen of this tick which he said came from his right ear of its own accord on the previous day On examination of this ear nothing abnormal was detected, and there was only a very small amount of wax The left ear, however, was completely filled with cerumen, and some soda drops were prescribed to soften it before removal Next day a considerable plug of wax and epithelium was syringed out, and on further examination a parasite similar to, but smaller than, the other specimen was plainly visible closely applied to the tympanum On touching it with a probe its four pairs of legs were freely moved, but it would not be coaxed to come out This condition was corroborated by Mr Herbert of Natal, who happened to be with me, and kindly saw my patient at the time Mr Herbert informed me that he had removed a tick from the tympanum of a little girl in Natal where such parasites are pretty common, but he had not seen an instance where each ear contained one

FIG 1



Pupa or Nymph of Argas (or Ornithodorus) Mégnini (Dugès) Ventral aspect. (Undistended specimen) Photograph × 6.

FIG 2



Dorsal aspect Arrow shows situation of stigmatic organ, described by Mr E G Wheler of Alnwick which is seen protruding on the other side Actual size of tick three-sixteenths of an inch long Photograph × 6.

animal. As it is very important not to leave any portion of the suckers or hooks in the tissues, more especially in the drum, I adopted his suggestion of soaking a small pledget of wadding with chloroform and inserting it into the canal for a few seconds the tick was rapidly killed and was easily removed by syringing. On examination it was found to be entire, and no injury was visible to the drum of either ear.

The previous history of the patient was that he had camped out in Arizona in the month of June. He returned to his home in Massachusetts, U.S.A., at the end of that month and then "had some curious sensations in the left ear, a sort of pain above the ear, and a rattling sound in the ear. These feelings decreased and had almost passed away, though the rattling was occasionally heard" up to August 25th when the live parasite came from the right ear, which apparently had not been the subject of any striking abnormal sensations. Cases of living animals in an auditory canal are not very uncommon, but the instance now recorded seems unusual in several respects. There was, in the first place, an absence of general or local ear symptoms sufficiently severe or annoying to necessitate a surgical examination previously to his visit to me. Again, the fact that each ear contained one specimen of the same species of tick is certainly curious, and the possibility of its living there and developing during a period of fully two months without producing more marked disturbance is remarkable. It was fortunate that the occupant of the right ear was free to crawl out and so to attract attention to the other ear, as it was certainly impossible for the parasite in the left ear to escape of its own accord on account of the ceruminous plug completely filling the auditory canal. It might, therefore, at any moment have seriously injured the tympanum if not so opportunely released. The question naturally arises, why the wax should have so rapidly accumulated in the one ear to the extent of occlusion and not in the other, when there was a similar and simultaneous source of local irritation to stimulate its secretion.

Mr. A. E. Shipley (Cambridge University lecturer) kindly forwarded my specimens to Mr. E. G. Wheler of Alnwick, who has been good enough to allow me to append his description of a stigmatic organ not hitherto observed in action. I am also indebted to Mr. Wheler for the photographs of the smaller parasite from which the accompanying illustrations are taken (Figs. 1 and 2). It is about three-sixteenths of an inch in length and the magnification of the photograph is slightly over × 6. The larger living specimen was more than double this size and broad and thick in proportion. In colour and general appearance its body resembled an unroasted coffee-bean. The smaller parasite, however, is best for purposes of identification and has been presented to the British Museum, which had, I understand, no similar specimen.

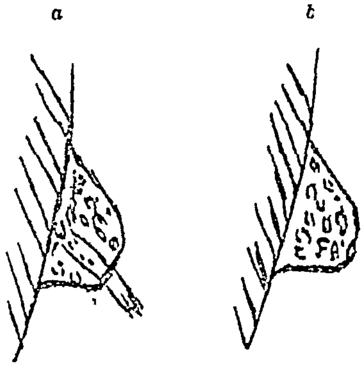
NOTE BY MR. WHELER ON A REMARKABLE STIGMATIC ORGAN IN THE NYMPH OF ORNITHODORUS (OR ARGAS) MÉGNINI (DUGÈS)

On my referring the above specimens to Professor Neumann of Toulouse he at once identified them as ornithodorus mégnini—a genus belonging to the argasidæ—but a careful examination showed a very remarkable difference from other members of that sub family of ixodidæ, such as may make it appear that another of those extraordinary variations of type may have come to light that have already made the study of these parasites unusually interesting.

The feature referred to consists of two protuberances placed in the position of the stigmata, one on each side of the body. They are situated above instead of behind the fourth pair of legs and are therefore visible from the dorsal side of the tick. These are entirely different from the stigmal plates or peritremes usually present and consist of cone-like projections pointing backwards. The top is truncate and perforated with a large hole. Through this in the living specimen was to be seen a pointed organ, projected and withdrawn at will, and with considerable rapidity (Fig. 3) This organ only partially filled up the orifice; it was furnished with three hairs at the end. Its appearance was somewhat similar to the final joint of the palpi. I am unable to satisfy myself as to its probable use. This special characteristic may possibly be deemed sufficient to establish a new genus for this species, in which case the name given by Marx, under the erroneous impression that it was a new species—rhynonoprium spinosum—may be adopted as being more appropriate than the older name given by Dugès.

The species has other peculiarities. It is fully described by Neumann in his "Révision de la Famille des Ixodidæ," and he mentions the unusual fact that the nymph attains dimensions at least as great as the mature female and that it is in this state that it acquires the greater part of the reserves of blood which the latter utilise to form their eggs. He also states that so great a difference exists between the two states as to have caused Marx to believe them to be separate species. Neumann had not, however, noticed the stigmatic organ above mentioned. In general characteristics the species appears to be nearer allied to argas than to ornithodorus, but it seems probable that it should be relegated to a separate genus—a contention that may be strengthened by the fact that the first joints of all the legs are almost totally concealed beneath the cuticle of the body, but not having had an opportunity of examining an adult specimen I should be sorry to express any definite opinion on the subject.

FIG. 3.



a, organ protruded. b, organ retracted.

It is interesting to note that Neumann's specimen came from a horse in Mexico, which strengthens the assumption that the present pair come from Arizona as described by the patient.

Cambridge.

A CASE OF BELLADONNA POISONING; MORPHIA USED AS AN ANTIDOTE.

BY PETER D. STRACHAN, M.A., M.B., CH.B. GLASG.

THE following case is of interest in that it affords an opportunity of estimating the tolerance of a child for belladonna and the efficiency of morphia as an antidote.

At 2 30 on the morning of March 7th, 1901, I was called to attend a boy, aged five years, alleged to have been accidentally poisoned by his mother. The parents' account was as follows. At 9.30 P.M. the mother gave the child a large tablespoonful of what she took to be syrup of senna. She then left home to nurse a sick relative and did not return till shortly before 2.30 A.M. About midnight the father, who slept with the boy, observed him to be breathing rapidly and was particularly alarmed at the loudness of the heart-sounds. He got up and took the boy out of bed and was still more alarmed to find that the child could not stand. Having been thus aroused the child became violently delirious, striking out with his fists, kicking, and biting on the slightest interference with his person. On being put back to bed he could scarcely be kept under the blankets on account of the violence of his movements. The father did his best to keep the boy quiet until the mother's return. When she saw the state of matters her suspicion of poisoning was aroused, and on examining the bottle from which she had given the dose she found it to be labeled "Poison." She therefore immediately sent for medical aid.

When I arrived I found the boy in the state described above. When left alone in bed he came out from under the blankets and wandered on hands and knees aimlessly about the bed, occasionally crying out. The delirium and violent movements were increased when efforts were made to control them. The movements were at no time convulsive. The face was flushed, not cyanosed. The pupils were widely dilated and failed to respond to light. The pulse and respiration were strong and rapid and the heart sounds were very loud. The boy was unable to speak. I found the suspected bottles to contain glycerine of belladonna. I ascertained that the boy had not vomited. As the evidences of belladonna poisoning were undoubted I washed out the stomach with the syphon. A good deal of the water first introduced was vomited over the child's nightshirt, which was of a dark brown colour, so that it was difficult to tell from its appearance whether it contained belladonna extract or not. That which came through the syphon was clear. There was no odour of belladonna from the washings. Considering that five hours had elapsed since the poison was taken I deemed it highly improbable that any of it still remained in the stomach.

After completing the washing of the stomach I gave a hypodermic injection of a quarter grain of morphia sulphate and a tablespoonful of castor-oil by the mouth, which was swallowed. In a short time the boy became quiet and I left the house, having directed the parents to send for me should any further alarming symptoms arise.

I was unable to see the patient again until 11 A.M. Then I ascertained that he had slept well till 10, and on awaking still exhibited symptoms of the same kind, but less aggravated. The delirium was now of a hilarious character, somewhat resembling drunkenness. The child laughed and chatted about his school experiences, games, fights, &c. The bowels had not yet moved. I then gave another hypodermic injection of one quarter grain of morphia sulphate and three grains of calomel by the mouth. The boy did not again sleep till about 11 o'clock. During the whole of that day somebody had to remain constantly at the bedside to keep him in bed. Several times he attempted to bite those trying to control his movements. Although the mouth was very dry and the tongue was constantly rolled about the boy refused food or drink and spat out whatever was introduced into his mouth. At two in the afternoon, the bowels not having yet moved, the mother gave a small soap-and-water enema, after which there were three or four liquid motions. The boy continued in the same mental state till about 11 P.M., when he fell asleep. Shortly after 11 P.M. I visited the patient, and finding him sleeping tranquilly I judged it best to do nothing. He had a good night's rest. The following morning at 10 I found him awake and presenting no abnormal symptoms except dilatation of the pupils which persisted for four days. No rash at any time appeared upon the body and there was no peeling of the skin. After recovery the boy seemed to have no recollection of the incidents which occurred during his illness.

This case may be regarded as illustrating two points, the one necessarily inversely as the other: (1) the tolerance of the child for belladonna; and (2) the efficiency of morphia as an antidote. 1. The dose swallowed was certainly a large one. The chief alkaloid in belladonna is now believed to be hyoscyamine, not atropine. These alkaloids are isomeric and it is considered probable that atropine is a conversion product of hyoscyamine. Extract of belladonna is estimated to contain about 1 per cent. of alkaloid. The glycerine contains 50 per cent. of the extract. In this instance fully half an ounce of the glycerine or two drachms of the extract were taken, representing about one grain of alkaloid. The medicinal dose of both alkaloids is from $\frac{1}{100}$th grain to $\frac{1}{30}$th grain. The fact that the patient remained untreated for five hours without exhibiting the extreme symptoms of poisoning by the drug points to a remarkable tolerance. Taylor quotes as remarkable a case in which a woman recovered after swallowing three drachms of the extract; but although emetics were administered successfully she did not completely recover until five weeks had elapsed. In the case under discussion, when we consider the enormous dose and the great probability that it was all absorbed, it would seem that tolerance alone can hardly explain the speedy recovery. 2. It is here interesting to note that "the Edinburgh committee, presided over by Dr. Hughes Bennett, conclude: (1) that sulphate of atropia is, within a limited range, physiologically antagonistic to meconate of morphia; (2) that meconate of morphia does not act antidotally after a large dose of atropia, and thus, while atropia is an antidote to morphia, morphia is not an antidote to atropia." Physostigmine, in relation to atropine, is considered to have a wider range of antidotal action than morphia. "Although it is experimentally proved that atropine can avert death from physostigmine the question yet remains unsolved whether physostigmine can prevent death from atropine." The above two quotations from Ringer and Sainsbury make it appear that atropine is a good servant, but a bad master.

Those who advocate morphia as an antidote to atropine recommend a quarter of a grain of the former to one-thirtieth of a grain of the latter. It is conceivable that in the child, where there is tolerance of the one and intolerance of the other, the proportion of morphia to atropine ought to be much less. In the light of the more modern view that hyoscyamine is the chief alkaloid in belladonna, these conclusions regarding atropine are irrelevant where belladonna is the poison under consideration, unless we assume that atropine and hyoscyamine have identical physiological action. Such an assumption stands in need of investigation, as indeed does the whole subject, for the opinions to be found in our text-books as to the alkaloids of belladonna and hyoscyamus, their antidotes, and their posology are very conflicting. The fact that in this case such large doses of morphia produced in the child so little of the usual effects of the drug is not so significant as it would at first sight appear, for it merely confirms, what is generally admitted, that belladonna antagonises morphia. The case for the converse proposition must rest entirely upon the non-appearance of the gravest symptoms of belladonna poisoning and the rapid recovery from those symptoms which did appear.

Auchinleck, Ayrshire.

DERMATITIS FROM ARSENIC IN STOCKINGS.

BY F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON;
AND
OTTO ROSENHEIM, PH.D., F.C.S.

THAT dyed materials when brought into contact with the skin may give rise to local irritation, occasionally culminating in actual dermatitis, has long been known to dermatologists. From the many cases available for quotation we need only refer here to those recorded in THE LANCET by Mr. Henry Lee.[1] In the early period of aniline dye manufacture the effect of dyed stockings in this direction was easily traceable to the large percentage of arsenic acid used in the preparation of these dyes (fuchsine red, &c.). That the external application of arsenic is productive of severe and even fatal poisoning is well established, as may be seen upon reference to the text-books of toxicology. These considerations, confirmed by many other observations, resulted in Germany in the passing of a law prohibiting the use of any dye stuff containing arsenic for the purpose of colouring food, wearing apparel, or domestic objects.[2] Since the passing of this law practically all the aniline colours placed on the market have been free from arsenic. A knowledge of these facts rendered the etiology of the following cases which have recently been brought under our notice at first sight somewhat obscure. We were, however, able clearly to trace them to the presence of arsenic in the stockings worn.

Before entering into the subject further, we think it best to give a short description of the cases in question. For the medical notes of the first case we are indebted to Dr. J. Cohn.

CASE 1.—"A boy, nine years old, complained on March 3rd last of pain in the right leg. Examination showed the presence of an inflammatory nodule of about the size of a walnut, situated at the junction of the upper with the middle third of the calf. The nodule was regarded as being probably a commencing furuncle, and sedative lotions and compresses were applied. Upon seeing the patient on the next morning each leg was found to be covered with from 10 to 12 nodules. The nodules were the same as the one observed on the previous day, except somewhat smaller, and were situated between the foot and the knee, stopping abruptly short where the stockings ceased to be in contact with the skin. This directed my attention to the stockings and upon inquiry it was found that the boy had put on a new pair of stockings on the same morning as the first nodule appeared. In the evening of the same day (viz., the second day of the affection) the boy was again seen. He was restless and since the last visit had vomited, without any apparent cause. His condition, however, did not seem serious, the temperature being normal and the pulse only slightly accelerated. There was no diarrhœa. The case caused no further anxiety but necessitated the boy being kept in bed for three days. The nodules gradually faded and on the fifth day the boy went out. On this day he was able to put on his stockings and wore one of his old pairs. On the eighth day, however, he put on the same stockings that seemed to have been the cause of the original irritation. They had been carefully washed in the meantime with soda. On the evening of the same day another crop of nodules appeared which faded in the course of a few days under similar treatment and the entire discarding of the stockings in question."

---

[1] THE LANCET, June 14th 1879, p. 856.

[2] Sell: Arbeiten aus dem Deutschen Kaiserlichen Gesundheitsamt, 1887; Erläuterungen zu dem Gesetzentwurf, &c.

CASE 2.—This case, which was much less severe, may be described as follows. The patient, a female, noticed a marked tenderness of the feet, especially the soles, after wearing for a few hours a pair of new black stockings. Although no gross local inflammation was produced the pain upon pressure was so intense that she could not stand or walk upon her feet. The stockings were discarded and the symptoms disappeared. A few days afterwards the same stockings, which had been washed in the meantime, were again worn with a recurrence of the symptoms, these latter again disappearing upon leaving off the stockings.

The clinical history of these cases suggests strongly the presence of some chemical irritant in the stockings. In Case 1 we were able to obtain for chemical examination (1) a pair of new stockings identical with those the wearing of which was followed by the dermatitis; and (2) the stockings actually worn by the boy after they had been twice washed. In Case 2 we obtained an unworn pair of stockings from the same lot as those which had caused the trouble. The stockings of the patient in Case 1 were long, black, machine-made woollen stockings, weighing 120 grammes; a piece of 100 square centimetres weighed five grammes. The colouring matter proved on examination to be a chrome black. The ash contained chromium and the material gave the reactions of logwood. Probably some other yellow colouring matter (fustic, &c.) was present. On further examination it was found that the stockings contained a considerable quantity of arsenic. Ten grammes treated by Reinsch's method gave a copious sublimate of large white arsenic crystals, and the residual liquid when submitted to Marsh's test gave still a strong black arsenical mirror. A further important result of the qualitative examination was that some of the arsenic was found to be present in a soluble form, since an aqueous extract of the stockings made at the temperature of the water bath, and subsequently subjected to Marsh's test, gave a strong arsenical mirror. In the case of these stockings we estimated the total amount of arsenic and also the amount soluble in water. These estimations were made by distilling with sulphate of iron and ammonia in a hydrochloric acid current,[3] and final weighing as pyro-magnesium-arsenate. It was found that one pair of stockings contained as much as 75 milligrammes, or 1·2 grains, of arsenic (As_4O_6); of this 10·5 milligrammes, or one-sixth of a grain, were soluble in water. A piece having an area of 100 square centimetres contained 3·1 milligrammes of As_4O_6. It was further found that the stockings which had been washed twice still contained some soluble arsenic, the watery extract giving a distinct arsenical mirror. After the stockings had been completely extracted with distilled water they still contained 64 milligrammes of As_4O_6. The stockings of the patient in Case 2 were only examined qualitatively. The mirrors obtained from both the stockings themselves and the aqueous extract of them were approximately of the same intensity as those derived under similar conditions from the new stockings of the patient in Case 1.

From the above results we think that the previously obscure etiology of these two skin affections is cleared up and that we may regard them as being caused by the arsenic contained in the stockings, and probably by the soluble moiety. The ordinary stockings worn by the boy in Case 1 in the time between the two attacks were found to be free from arsenic. It must, of course, be remembered in this connexion that the term "soluble" and "insoluble" with regard to the arsenic content of the stockings is only relative, in that the stockings while being worn would be subjected to the action of an acid secretion—namely, the sweat—by the agency of which some of the insoluble arsenical compounds might be rendered soluble. The fact that the amount of sweat secreted, especially by the feet, is very considerable, is shown by the researches of Cramer,[4] who found that socks in a given time absorbed their own weight of sweat. In this case the conclusion that some arsenic was absorbed through the skin seems justified, in that we must regard the vomiting as produced by the excretion by the stomach of arsenic absorbed by the skin. This same phenomenon has been recorded by other observers.

We have heard incidentally of other cases of dermatitis which, in the light of our present knowledge, we should regard as having a similar etiology to the above. Unfortunately these have not been observed with sufficient exactitude, nor was the material in question available for chemical examination. The indications, however, were sufficient to induce us to examine this matter further, with the view of ascertaining to what extent ordinary dyed goods contained arsenic.

We first examined three samples of black woollen stockings purchased at various prices in different parts of London, all emanating from the same wholesale firm and from the one which supplied the original stockings worn by the patient in Case 1. They all contained arsenic, but apparently in smaller amount than the stockings productive of the dermatitis. We next obtained one sample from each of four other makers, and we found that arsenic was present in each case to a larger or a smaller degree. Three samples of "tan" mixed wool and silk socks were contaminated as well. We examined also a pair of ordinary woollen gloves and found them to be arsenicated. This had especial interest in view of the case quoted by Sell[5] in which a severe dermatitis of the hands was produced by the wearing of a pair of marine blue gloves. A sample of black loose wool was found to be free from arsenic.

Upon inquiring into the source of the arsenic in the goods examined by us we found that arsenic in various forms is used in the process of dyeing In the standard work on dyeing by Knecht and Rawson[6] it is stated that a solution of white arsenic in acetic acid to which some glycerine has been added is used and called "purple fixing colour." The authors also say[7] that "sodium arseniate is extensively used as a fixing agent for mordants. In yarn dyeing it affects the hands of the workmen owing to its poisonous properties. As it is so dangerous ...... its use is objectionable." Another possible source, although more unlikely, would be the use of highly arsenicated sulphuric acid in the preparation of the chromic acid mordant bath.

The use of arsenical mordants has been recognised to some extent by the German law quoted above. Their use is allowed upon two conditions—namely, that no *soluble* compound of arsenic be present in the finished article, and that the total quantity of arsenic be always less than two milligrammes per 100 square centimetres.[8] A similar law exists in Austria. In Sweden the law is much more stringent. The materials used for the manufacture of wearing apparel, &c., must not contain arsenic to such an extent as to allow 100 square centimetres of the finished article to produce when treated according to a certain test an opaque arsenical mirror. The maximum limit, according to this test, corresponds to about 0·07 milligramme per 100 square centimetres.

It will be seen that the stockings which caused the dermatitis in our two cases contained arsenic considerably in excess of the amount allowed by the above-named countries, and although no doubt individuals differ largely *inter se* with regard to their sensitiveness to arsenic it would seem that if arsenical mordants cannot be dispensed with, their use should at least be supervised. The presence of soluble arsenical compounds in those materials which come into intimate contact with the skin can certainly be avoided, and should be prohibited.

[8] In this connexion it is interesting to know that a pair of black silk socks and a pair of yellow stockings obtained from Germany were found to be free from arsenic

TETANUS PUERPERALIS.

BY KEDARNATH DAS, M.D.,
TEACHER OF MIDWIFERY, CAMPBELL MEDICAL SCHOOL, CALCUTTA.

THE rarity of this terrible and almost fatal complication of the puerperal state warrants publication of the following successful case. Tetanus is known almost from time immemorial, and has been studied by scientific men of all ages; but it is only since the discovery of the specific bacillus by Nicolaier in 1884 that its study has received a scientific foundation. At the present day we must define tetanus as "an acute infectious disease which is invariably and indubitably caused by the entrance into the system of the specific micro-organism—the bacillus tetani of Nicolaier and first cultivated in pure culture by Kitasato in 1891 in anaerobic medium." In the present light of bacteriology and animal experiments there is certainly no place in the description of a given case of tetanus for the diagnosis "idiopathic" or "rheumatic." The only interpretation that can be put is that in these cases the point of infection has not been well searched for or found. The so-called varieties only indicate the seat of infection, the "puerperal" variety thus indicating that a breach in the parturient tract is the point of infection.

A Hindu female, aged 28 years, was delivered of a full-term child on July 20th, 1900. The child had trismus neonatorum on the tenth day and died within 24 hours. The mother had lock-jaw and stiffness of the neck since July 30th. She was admitted into the Campbell Hospital, Calcutta, on August 3rd, 1900, when she had well-marked symptoms of tetanus—opisthotonos, jaw completely locked, spasms very frequent, constipation, pulse 120, small, and compressible, and temperature 100·2° F. She was at once given an intra uterine douche of perchloride of mercury lotion (1 in 2000), an ordinary soap-and-water enema, followed by an enema of 40 grains of chloral hydrate and five grains of calomel on the tongue. She was subsequently kept under the influence of chloral, the drug being given per mouth or rectum. Occasionally she had to be given very large doses of it and during one night she had three enemata of 40 grains each. During the course of the illness she was given apomorphia four or five times hypodermically in addition to chloral per rectum when she could not take medicine by the mouth. I also had recourse to intra-cellular injection of normal saline solution (under the breasts) several times during the course of the illness with a view to help elimination of the toxins The spasms did not completely abate till Sept. 18th—i.e., six weeks after admission. The bowels were kept well open. Plenty of liquid food was given regularly. The total quantity of chloral used was eight ounces, six drachms, and ten grains. She had in addition as much bromide of potassium and a quantity of tincture of Indian hemp.

The prognosis is very grave. The average mortality of tetanus, taking all the so-called varieties together (as given in English text-books), is between 80 and 90 per cent. Garrigues has collected 57 cases of puerperal tetanus and the mortality is put down between 84 and 92 per cent. (*vide American Journal of Obstetrics*, 1882). I have been able to collect 68 cases from literature, a tabulated list of which is given below. In compiling this I have excluded all cases in which there has been any doubt with regard to diagnosis. Of these 68 cases only five patients recovered, giving a mortality of 92 per cent. The cases can be subdivided into three groups. In the first group (i.e., Cases 1 to 43) we have cases collected from English text-books and periodicals. Of the 43 cases three patients recovered, or a mortality of 93 per cent. In the second group (i.e., Cases 44 to 64) we have cases treated with antitoxin given either subcutaneously or by intra-cerebral injection. Of these 21 cases one patient only recovered (treated with intra-cerebral injection + chloral + morphia), or a mortality of 95 per cent. In the third group (i e., Cases 65 to 68) we have Indian cases collected from the *Indian Medical Gazette* of the last 35 years. Only four cases of unmistakeable puerperal tetanus have been found, with one recovery, or a mortality of 75 per cent. It may thus be seen that even with the best modern treatment the mortality of puerperal tetanus is appalling. It must, however be remarked that the Indian cases seem to yield to treatment better than the other cases.

must look to the following points: (1) to destroy the bacteria at the seat of infection by thoroughly anti-septicising the parturient canal and by subsequently keeping it aseptic; (2) to eliminate the toxins already absorbed by brisk purgation and intra-cellular injection (under the breasts) of normal saline solution; (3) to overcome the symptoms induced by the action of toxins—viz., the increased reflex irritability of the higher nerve centres—and this is best accomplished by keeping the patient absolutely quiet in an isolated place and by chloral in very big doses, given either per os if possible, per anum, or hypodermic injection of apomorphia, hyoscine hydrobromate, or morphia; and (4) to neutralise the poison already absorbed and to immunise the body after local infection has taken place. Both of these indications ought theoretically to be met by the injection of the serum of immunised animals. But the mode of action of the antitoxin has not yet been acceptably explained. Moschcowitz, in his masterly contribution on the antitoxin treatment of tetanus, published in the Annals of Surgery of August, September, and October, 1900, gives no very decided opinion with regard to the neutralising effect of antitoxin, after a careful analysis of 358 cases. Antitoxin treatment, he says, appears to have a distinctly beneficial influence on the course of tetanus and the statistics he has collected show that with this treatment the general mortality of tetanus has been reduced from 90 to 40 per cent. But the puerperal cases, taken separately, show no improvement in the percentage of recoveries With regard to the question of immunising the body after local infection has taken place, this would involve the injection of antitoxin as a prophylactic measure in all wounds when there is reason to suspect the possibility of the subsequent development of tetanus. By such treatment it is asserted that an extensive epidemic of puerperal tetanus in a lying-in hospital at Prague was cut short and numerous instances of good results from a similar course have been recorded in veterinary practice.

Calcutta.

MERCURY AND IODIDE OF POTASSIUM INTERNALLY GIVEN WITH PILOCARPINE HYPODERMICALLY IN DISEASE OF THE EYES.[1]

BY G. HERBERT BURNHAM, M.D. TOR., F.R.C.S. EDIN.,
ASSOCIATE PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY AT THE UNIVERSITY OF TORONTO, TORONTO, CANADA.

CASE 1.—In August, 1899, a patient consulted me regarding an inflamed condition of the right eye. I found at the upper and inner part of the eyeball in the ciliary region very severe scleritis, limited, and the patch of exudation large, swollen, and deeply congested. The adjacent cornea was infiltrated with a cloudy opacity up to, and slightly beyond, the pupillary margin, and there were much pain, photophobia, &c. I gave for ten days mercury and iodide of potassium and used atropine locally. The severity of the symptoms was relieved, but the progress of the sclero-keratitis was not stayed.

Early in September, 1899, I began treatment. The scleritis was now more extensive and the cornea was infiltrated almost throughout its whole extent. I gave pilocarpine daily in doses of one-sixth of a grain for two weeks, and then at intervals of from four to six weeks for seven injections, one each day, and have so continued up to the time of writing. The iodide of potassium and mercury have also been continuously used. The scleritis has traversed the whole ciliary zone up to the point of beginning, but under most favourable conditions—that is, the part first affected has been the most severely attacked and every adjoining part taken in was less severe, till finally, when the disease came again to the inner canthus, it was merely a blush. Moreover, the previously affected parts have kept improving and have never relapsed. In January, 1900, the sclero-keratitis was cured, but there was left a decided corneal haze, interfering very much with vision so that nothing could be read at 20 feet. The treatment was no longer necessary in regard to the scleritis, but it had to be kept up so as to clear up the cornea and thus to restore normal vision. This is being done, and now the vision is $\frac{20}{60}$. The cornea is still clearing up and I fully expect almost or quite normal vision again. There has never been any sign of a return of the disease, and the appearance of the formerly severely inflamed sclera is now normal.

The prognosis regarding this form of sclero-keratitis is gloomy. It is stated in our best text-books that the treatment is at best but palliative; the disease is certain to relapse and continues in this way for years till finally vision is not only impaired or practically lost, but ciliary bulging takes place, leading to marked staphylomatous changes. Under the combined treatment of mercury and iodide of potassium internally and pilocarpine hypodermically there need be, I think, no such result, but a permanent curative effect may be secured. The patient's history is tuberculous.

---

[1] A paper read at the thirty-third annual meeting of the Canadian Medical Association held at Ottawa on Sept. 12th, 13th, and 14th, 1900.

CASE 2.—The other case is that of a boy, aged 12 years, suffering from acute sympathetic ophthalmia—that is, a very severe cyclo-irido-keratitis. When the sympathetic trouble, which showed itself rapidly, was first noticed, the other eye, which had been injured by a penetrating wound, extending well up into the cornea from just at the ciliary region, was excised, the date being Jan. 25th, 1900. Under atropine the pupil at once became fully dilated. Mercury and iodide of potassium were given and the eye at first improved. On Feb. 2nd, eight days after the excision, the sympathetic inflammation again plainly showed itself. I now began combined treatment. For the first 12 injections of pilocarpine, that is the first two weeks, the effect was not full, though I gave as much as one sixth of a grain. I felt that there was some reason for this, for one sixth of a grain is a very large dose for a boy 12 years old. The throat was very slightly affected by the atropine and apparently there was no noticeable constitutional effect. However, I stopped, by more careful pressure upon the canaliculi, all passage of it into the throat when one tenth of a grain gave a full effect. The pupil was now, at the end of three weeks only, dilated one third, the exudation into the ciliary region and iris tissue causing the narrowing to take place. The pupillary margin was very firmly bound down and the capsule of the lens in the pupillary area was covered with a semi-translucent coating of lymph. On the 24th, four weeks since the excision and about three weeks since the beginning of the combined treatment, another acute attack came on and the condition was as follows. There was much general infection, the tension was +1, there was severe pain, and keratitis punctata was present throughout the whole cornea—in fact, a well-developed case of sympathetic cyclo-irido keratitis; there was perception of light only. Under the usual prognosis with respect to similar cases there was a very hopeless outlook. On the 27th the eye was quieter; the tension was +. On March 20th the eye was still improving and vision was better. The combined treatment was still kept up and the eye kept doing well till the 23rd when there occurred a very acute exacerbation with severe pain; the tension was + 1 and there was perception of light only. On the 31st the eye was better. Between this date and the beginning of September the combined treatment was kept up. An improvement which was most uniform, thorough, and unbroken by any symptoms of relapse resulted. The sight also gradually improved till now (Sept. 6th, 1900) the vision is $\frac{16}{16}$ less two letters. The absorption has continued very satisfactorily so that the pupillary margin has given way throughout almost its whole extent. The pupil, however, is dilating very slowly, due to the exudation into the iris tissue. This absorptive process I confidently believe will continue till finally the whole of the affected region will again be restored to a healthy condition. The tension is now normal. This is the first case of acute sympathetic ophthalmia which I have had the opportunity of treating in this way, and the results at the end of about eight months fully convince me that the result will be for all practical ends an eye normal as regards vision and its general condition. This boy has taken internally ever since Feb. 2nd, 1900, five grains of iodide of potassium thrice daily after eating and the twenty-fourth of a grain of bichloride of mercury before eating. One-tenth of a grain of pilocarpine was given hypodermically every second day after the first two weeks for five months continuously. During the remainder of the eight months at the end of every two weeks I have given an injection every second day for six injections and am still going on with them. His general health is good.

Other cases previously published by me,[2] added to those now given and also many minor ones not reported, have given results better than those obtained by other treatment so that I feel justified in advocating the superiority of the combined form of treatment. During four years as resident house surgeon at Moorfields Eye Hospital I saw a good many cases of sympathetic ophthalmia, and I am persuaded that under any other treatment the result in Case 2 would have been that, under the best of circumstances, the eye would have been greatly impaired. The treatment may be said to owe its efficacy to its power of arousing to excessive activity, in a vigorous and sustained manner, the normal physiological processes in diseased tissues, and thus acting so in accord with the efforts of nature as to bring about a restoration to a normal condition. I am now using this treatment, in this belief, in a case of double conical cornea with so far very encouraging progress.

ST. THOMAS'S HOSPITAL

A CASE OF INFLAMED CYSTIC OVARY WITH PELVIC CELLULITIS AND PERITONITIS WITH DEVELOPMENT OF SEPTICÆMIA SUCCESSFULLY TREATED WITH ANTI-STREPTOCOCCIC SERUM.

(Under the care of Dr. W. W. H. TATE.)

IN the following case the evidence of the value of anti-streptococcic serum is very strong, in spite of the fact that the patient refused to allow the blood to be examined bacteriologically. Even, however, if the patient will not permit an examination of the blood, much information may be obtained from a bacteriological examination of the uterine cavity. W. Williams[1] examined 44 cases of puerperal fever and streptococci were found in only eight of these. Most observers are agreed that the evidence is against anti streptococcic serum being of much value except in isolated cases, yet as the injection very rarely appears to be in any way harmful it would be well to give the serum an extensive trial, a bacteriological examination of the blood being made whenever possible. For the notes of the case we are indebted to Mr. Hanway R. Beale, senior obstetric house physician.

A married woman, aged 37 years, was admitted into St. Thomas's Hospital on Oct. 13th, 1900, under the care of Dr. Tate. The patient had had 10 children and no definite miscarriages; her last child was born three years ago; the confinements had been normal. The present illness began in July, 1899, three weeks after a menstrual period, when the patient had a sudden flooding after lifting a tub; she supposed that she lost three pints of blood. The vagina was plugged, but the hæmorrhage persisted for three weeks, when some operation was performed at a cottage hospital where she stayed one month. The patient thought that she was pregnant at the time. On Oct. 4th there occurred a discharge of blood and yellow matter of offensive odour, and in November a second operation was performed similar to the previous one. At this time there was also frequent and painful micturition. The operation was followed by a high temperature and severe abdominal pain lasting six weeks; in December the uterus was curetted, and two weeks later a perineal abscess was opened. After this she was well until June, but she did not menstruate during this period. Menstruation commenced after one week's severe abdominal pain. In July a lump was noticed in her right side but operation was not deemed necessary. In September frequency and pain on micturition became continuous and pain in the lower part of the abdomen was worse. She was seen by Dr. B. H. Kingsford of Woking, who diagnosed pelvic cellulitis and sent her to St. Thomas's Hospital.

On admission into St. Thomas's Hospital she was found to be of cachectic appearance and complained of great pain in the lower part of the abdomen and pain and frequency of micturition. There were great tenderness just above the symphysis pubis and a sense of fulness and great tenderness about the right flank, and there was a resistant tender tumour of about the size of a tennis-ball in the hypogastrium just to the right of the mid-line. Owing to the tenderness she was examined under an anæsthetic by Dr. Tate and the condition found per vaginam was as follows. The cervix uteri was directed backwards. The external os was patulous and the lips were rather œdematous. The body of the uterus was fixed and appeared to be in the middle line. On the right side of the uterus there was a hard cartilaginous mass extending outwards to the pelvic walls and reaching just above the brim of the pelvis, evidently the result of cellulitis. The mass extended forwards into the anterior quarter of the pelvis and apparently into the cellular tissue between the cervix and bladder. On the left side there was a smaller swelling extending backwards from the side of the uterus to the lateral pelvic wall and quite fixed. The anterior vaginal roof was found to be slightly depressed and to have a boggy feeling. Nothing abnormal was found in the heart and lungs. The urine was alkaline and contained pus and traces of albumin. There was no sugar. The specific gravity was 1024 (catheter specimen). The tongue was slightly furred.

---

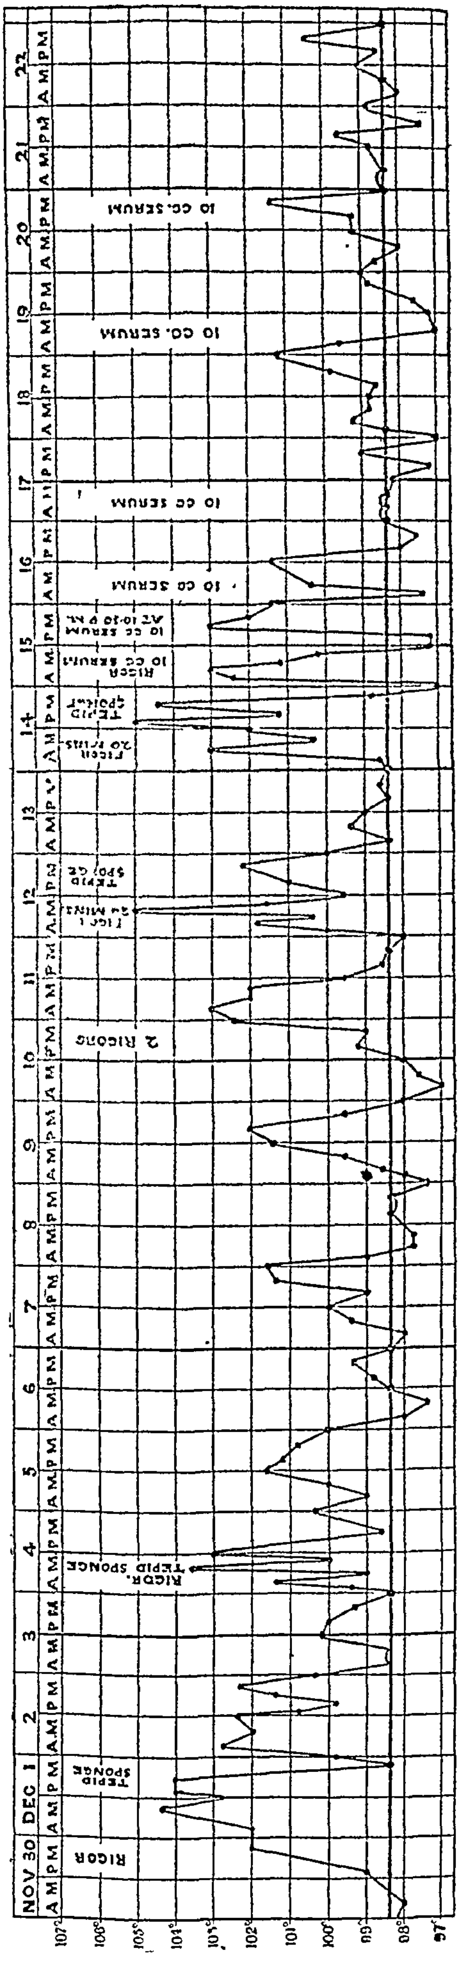
[2] Archives of Ophthalmology and Ophthalmic Review.

[1] American Journal of Obstetrics, September, 1900.

From Oct. 13th to Nov. 6th the patient was kept quiet in bed, during which time she suffered a good deal from pain in the lower part of the abdomen, this at times being very severe. Micturition was frequent and painful. The temperature during this period varied from 98·8° to 100·6° F., once reaching 102°. As it was thought possible that there was a collection of pus in the cellular tissue between the cervix and the bladder ether was administered and a further examination was made, when it was found that the mass previously felt on the right side of the uterus had diminished in size slightly but was still of a cartilaginous consistence and was immoveable. On the left side there was now only a slight thickening in the situation of the broad ligament which was slightly moveable up and down. Anteriorly a swelling could be felt in the situation of the bladder causing some bulging of the anterior vaginal wall and probably the result of cellulitic thickening about the wall of the bladder.

By the introduction of a sound the uterus was shown to be slightly retroverted. Adherent to, and above the level of, the fundus there was a rounded swelling of about the size of a cricket-ball and having the consistency of a sub-involuted uterus but apparently moveable to a slight extent on the anterior surface of the uterus. The sound did not appear to enter this mass. The cervix uteri having been drawn down by means of a volsellum, an incision was made with scissors through the mucous membrane of the vaginal fornix just above the cervix. The finger was then inserted through the incision into the cellular tissue between the uterus and the bladder in order to give an easy exit to any pus which might be present. None was evacuated and the opening made was plugged with iodoform gauze. The temperature fell after this but rose again next day and continued to vary from 99° to 101° and 100·6°. A rigor occurred on Nov. 9th, and the patient had a good deal of pain in the lower part of the abdomen. As she had not improved with rest and it was considered that the inflammatory mischief justified interference it was decided to make an exploratory laparotomy.

The operation was performed on Nov. 15th. On opening the abdomen evidence was found of considerable pelvic cellulitis and peritonitis. The uterus had been drawn down to the left side and fixed. The left ovary and tube were healthy; the right tube, although thickened and the fimbriæ œdematous, was also healthy. In the situation of the right ovary there was a spherical tumour of the size of a tennis ball and entirely covered by peritoneum except at its attachment to the broad ligament which was continued for a considerable distance down the pelvis and was flattened from side to side. As there did not seem to be sufficient disease in the abdomen to account for the patient's condition a further examination was made of the parts in front of the uterus by the combined abdominal and vaginal method and with the assistance of the bladder sound a swelling was now localised between the cervix and the bladder evidently containing pus. The abdominal opening was now temporarily closed with sterilised gauze and a bistoury was introduced through the old scar in the vagina and a deep incision was made through its anterior wall just below the fornix, giving exit to about two ounces of creamy, non-offensive pus. The abscess cavity and the vagina were irrigated with sterilised water and were plugged with iodoform gauze. The operators having been re-sterilised and the instruments changed the abdominal operation was



resumed and the ovarian tumour was removed. As there was persistent slight hæmorrhage from the œdematous tissues a thin gauze plug was inserted and the wound was closed. Examination of the parts removed showed that the tumour consisted of an outer soft œdematous ovary containing numerous Graafian follicles and an internal cyst which was easily enucleated and on incision was found to contain sanious fluid in which floated masses of pale translucent lymph; its walls were a quarter of an inch thick and were coated with inflammatory lymph

From Nov. 16th to the 22nd good progress was made; the stitches were removed on the 22nd, the wound looking clean and there being apparently good union. On the 24th there was much abdominal pain and an area of dulness was found over a slight swelling in the lower part of the abdomen behind the wound. Fluctuation and great tenderness were found over it. On the 26th these had increased and the temperature had risen to 100 4° every day since the 23rd. Accordingly an incision was made in the swelling under nitrous oxide gas and 14 ounces of creamy inodorous pus were evacuated, and a drainage tube having been inserted the wound was dressed with hot boric acid lint. This was followed by a fall in the temperature and by general improvement until the 30th, when the tube was discarded, there being very little discharge In the evening of this day there was a rigor and the temperature rose to 102° and continued to be remittent, as can be seen from the chart. Tepid sponging was ordered whenever the temperature arose above 103 4°. A second rigor occurred at 5 A.M on Dec. 4th, on which date the abdomen was quite flaccid and there was no indication of pus anywhere The urine was neutral, of specific gravity 1012, and contained no albumin, pus, or sugar. Further rigors occurred on the night of the 10th and on the 11th The blood count showed that the red cells numbered 4,800,000 per cubic millimetre and the white cells 57,600. Nothing abnormal was detected on examination of the heart and lungs; the pulse was 108, full, and of low tension. Per vaginam there was felt a hard mass on the right side in the situation of the broad ligament passing backwards in the pelvis to the utero-sacral ligament. There was a smaller mass in the left broad ligament. The uterus was fixed. By abdomen the spleen was felt to be enlarged. Another rigor occurred on the 12th with a rise of the temperature to 105°. Examination of the heart revealed a soft blowing systolic murmur at the apex and a slight friction sound just after systole over the sternum at the level of the fourth rib. There was no increase in the pericardial dulness The spleen was felt one inch below the costal margin. Pain was felt in the right shoulder and sterno-clavicular joint and the latter was swollen and reddened and evidently contained fluid.

Up to Dec. 15th the patient's condition was obviously getting worse. On this day the injection into the flank of anti streptococcic serum in doses of 10 cubic centimetres was commenced, a blood examination for culture purposes previously to doing so being refused. Further injections of 10 cubic centimetres of serum were given on the 15th, 16th, 17th, 19th, and 20th, six in all, the temperature fell immediately after each and no rigors occurred after the first injection. From the 20th the patient steadily improved and recovery was uninterrupted, the temperature finally falling to normal on Jan. 3rd, 1901 An urticarial rash had appeared on Dec. 28th, but was very transient. The patient was discharged on Jan 16th feeling well; the appetite was good and the bowels were acting regularly. The pain had gone from the shoulder and the sterno-clavicular joints and there was only slight stiffness on movement. She could walk well without support. Vaginal examination showed evidence of the cellulitis, but most of the swelling had gone down and there was only a little thickening.

Remarks by Mr. BEALE—Until recently the treatment of septicæmia has been limited to removing the origin of the poison, if possible, leaving the rest to the *vis medicatrix naturæ* and at the same time trying to aid the resistance of the body by the exhibition of stimulants. To be sure that a particular case is in reality one of streptococcal septicæmia the only infallible method is to make cultures from the blood on nutrient media and to have them examined by a bacteriologist. Unfortunately in this case permission to do so was rescinded at the last moment, and the anti-streptococcic serum was administered on the supposition that the case was one of septicæmia judged by the history and clinical signs. I think that I shall be able to show that these make the diagnosis quite clear.

The case commenced with a hæmorrhage from the uterus, possibly due to a miscarriage, which was allowed to continue for three weeks and was then followed by some manipulation, the nature of which I am unable to determine, but whatever it was it would give an opportunity for septic infection. This was followed shortly afterwards by a purulent discharge and the occurrence of pelvic cellulitis and by collections of pus in the pelvis and ovary. Passing on to the time when the septicæmia is supposed to have become evident we find a sudden rigor on Nov 30th, followed by a rise of temperature to 104 4°, and from this point the fever continued to be intermittent, another rigor occurring on Dec. 4th and again on the 12th, and a succession on the 14th and 15th. This, with the facial aspect and attitude and the presence of the enlarged spleen and diarrhœa, indicated that she was suffering from an extreme toxæmia. In addition to these, in septicæmia in all but very slight or rapidly fatal cases we should expect a leucocytosis, which was present in a marked degree This, with the absence of a characteristic eruption and a continued fever, served to distinguish it from typhus and enteric fevers the only two causes from which any difficulty of diagnosis could arise. In addition to the foregoing we have the development of a cardiac murmur and the joint condition as evidence in favour of septicæmia.

Considering now the reaction to treatment with anti-streptococcic serum we find that the behaviour of the temperature is remarkable, for each injection of serum was followed very soon by a rapid fall and a decline in the fever, till on Dec. 17th there was none. No serum was given after noon on the 17th and none at all on the 18th, but that night the temperature rose to 101°, and fell again after injection and similarly on the evening of Dec. 20th, after which it showed no tendency to rise much above 100°. This behaviour clearly points to cause and effect, for it can hardly be supposed that the considerable fall after each injection was a mere coincidence. The urticarial eruption which appeared on Dec. 21st was either the result of the septic poisoning or of the injection of the serum, and in this respect resembled the erythematous eruptions so often seen in diphtheria wards. It is interesting to note that there were no disagreeable sensations experienced by the patient after any injection except pain at the site, nor were there any collapse symptoms. I think that the foregoing facts clearly show that the case was one of septicæmia and that it was cured by the administration of anti-streptococcic serum.

I am indebted to Dr. Tate for permission to publish the case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Arterial Hæmorrhage from the Ear and its Control by Ligature of the Common Carotid.—Acute Leukæmia.

A MEETING of this society was held on April 23rd, Dr. F. W PAVY, the President, being in the chair.

Mr. WALTER G SPENCER read a paper on Arterial Hæmorrhage from the Ear and its Control by Ligature of the Common Carotid Artery. He considered in this paper cases of severe, recurring, and ultimately fatal arterial hæmorrhage from the ear in cases of suppurating otitis media. Such cases were shown by post-mortem examination to be due to ulceration into the internal carotid artery at, or close to, its curve in the petrous bone All these were necessarily advanced cases in which the prospects of surgical interference appeared to be unfavourable; but if all the recorded cases were considered it was shown that they fell into three groups 1 Cases entirely unfavourable on account of being secondary to pulmonary tuberculosis, in which, although the hæmorrhage might be controlled, yet death ensued sooner or later from the pulmonary disease. 2 Cases of chronic ear disease which by modern methods were preventable by a timely operation on the middle ear and antrum. Perhaps also large doses of mercury had bad effect in some of the older cases. 3. In a third group of recent cases arising after acute inflammation in children the hæmorrhage had been successfully controlled by ligature of the common carotid. In the absence of post-mortem evidence the source of the hæmorrhage was conjectural, but it came most probably from the carotico-tympanic twig close to its origin from the internal carotid artery in the carotid canal. A clot might form in the proximal end of this branch after the ligature and so prevent retrograde hæmorrhage. When, however, the disease extended from this branch to the wall of the artery itself so as to perforate it, it was unlikely that any clot would be sufficient to restrain the retrograde hæmorrhage. A summary of many of the recorded cases, illustrative of these several groups, was given, and one under the care of Mr. Spencer was narrated. In the first and second groups ligature of the common carotid was advisable as a palliative measure, but cases in the third group were regarded as the most favourable for operation. The common carotid should be selected for ligature, not the internal, for many reasons.—Mr. W. MACADAM ECCLES remarked on the rarity of such cases as that recorded by Mr. Spencer. He asked—Had there been any other treatment of the ear after the hæmorrhage? Would Mr. Spencer advise ligature in all of these cases instead of other measures? What was Mr. Spencer's experience of ligature of the carotid in young subjects for conditions other than ear disease? In a child, aged two years, he (Mr. Eccles) had recently tied the carotid for hæmorrhage from the neck after removal of caseous glands. It was, of course, a serious procedure both in its immediate and remote effects.—Mr SPENCER, in reply, said nothing was done to the ear of his patient for some time after the hæmorrhage. As to other methods of treatment, plugging, though usually tried, was of no use—the plug was generally forced out. Mr. Spencer then referred to some other conditions which rendered ligature of the common carotid necessary.

Dr. ARTHUR G. PHEAR narrated the particulars of a case of Acute Leukæmia. The patient was a man, aged 21 years, who after a few weeks' illness was admitted under the care of Dr. Alexander Haig at the Metropolitan Hospital. The leading symptoms of his illness were (1) marked and increasing anæmia; (2) fever of moderate degree; (3) stomatitis, affecting chiefly the gums, which were swollen, spongy, and later ulcerated; (4) enlargement of the lymphatic glands, limited at first to the submaxillary and cervical glands, afterwards involving the glands generally; (5) moderate enlargement of the spleen; and (6) a special kind of leukæmia. The blood contained 404,000 white corpuscles per cubic millimetre, the proportion of white to red corpuscles being one to three. The normal forms, excepting the basophile cells, were all involved in the increase. Abnormal forms were present in large numbers, consisting chiefly of large cells, each with a single voluminous nucleus, differing from myelocytes in the absence of neutrophile granulation. At the post-mortem examination there were found a persistent thymus gland, enlarged lymphatic glands, superficial and deep, and enlargement of the tonsils and of the spleen. The lymphoid follicles of the large intestine were swollen and ulcerated, the bone-marrow from the femur was opaque and pink in appearance and firm in consistence, and the marrow-juice abounded in cells similar to the large mononuclear cells of the blood. The microscopic examination disclosed a widespread overgrowth of lymphoid tissue in which the preponderating cells were not similar to those of normal lymphoid tissue, but consisted of large mononucleated cells closely resembling the abnormal leucocytes that during life had been found so abundantly in the blood. Microscopic specimens from the case were exhibited.—Dr. J. ROSE BRADFORD remarked that they knew very little of the nature of acute leukæmia. He believed, however, that it might be less rare than was generally supposed. It was often discovered by accident. The malady simulated a stomatitis, or, as in one case which he had seen, malignant disease of the lower jaw. Such cases certainly emphasised the necessity of a more systematic and routine examination of the blood. Three symptoms, purpura, stomatitis, and pallor together, should make one suspect the disease. Was acute leukæmia, he asked, of an infective nature arising in the mouth? It was a curious circumstance that the excess of lymphatic tissue seemed to lead to a diminution of the normal forms of leucocytes. The case before the society was no doubt a genuine case of acute leukæmia. In future cases it would be of interest to see if the blood or marrow of the bones contained any parasitic protozoa.—Dr. CHARLES REISSMANN remarked that the case brought before the society by Dr. Phear was one of interest because cases of lymphatic leukæmia such as this were much less common than cases of myelogenic leukæmia. Comparing these two conditions, he remarked that in the latter the cells which were found in increased numbers in the blood were the granular leucocytes, those forms which were known to react to chemiotactic stimuli. They were cells which had the power of spontaneous locomotion, and Ehrlich considered myelogenic leukæmia to be an active leucocytosis. In lymphatic leukæmia, however, there was an increase, not of the granular leucocytes, but of the non-granular, non-amœboid lymphocytes. These were not known to react to chemiotactic stimuli. Their number was increased in the blood when an alteration took place in the circulation of lymph through lymphoid tissue. Thus it occurred during digestion, when there was an active circulation through the lymphatic glands of the intestine. So also it occurred as the result of pilocarpin injections This, then, might help to throw light on the pathology of lymphatic leukæmia. Turning to the question whether this disease might be due to a parasite Dr Reissmann referred to Löwit's observations, the latter having found certain bodies in the blood of myelogenic leukæmia which he termed parasites. In a case of this nature now in the Middlesex Hospital Dr. Reissmann had found these bodies. But they occurred chiefly in the mast-cells. Using the same method of preparation of films he had found similar bodies, though smaller, in the blood of healthy rabbits and he believed them to be mast-cell granules swollen out and deformed during the process of staining. A small quantity of blood from the patient referred to was injected into the vein of a rabbit by Mr. A. G. R. Foulerton for Dr. Reissmann. The rabbit died a few days later but no changes were observed in its blood. It was, nevertheless, possible, and even probable, that both forms of leukæmia might be due to a parasite, and if so in lymphatic leukæmia the point of entrance was very probably the mouth.—Mr. SPENCER remarked that many of the cases belonging to this group of disorders ran one into another. They were probably due to parasitic infection. As to the point of entry, the glandular enlargements were some guide, but there seemed some evidence that the tonsils or the intestinal mucous membrane might also be the portal of entry.—Dr. THOMAS BARLOW remarked that one of the most interesting features of this case was its possible mode of origin. There was stomatitis in Dr. Phear's case. He (Dr. Barlow) referred to the case of a boy, aged six years, who was admitted to hospital for inflamed tonsils; they were sloughy-looking but were not diphtheritic. Later he developed hæmorrhagic stomatitis. Enlargement took place in the glands around the jaw and also the spleen and lymphatic glands in different parts of the body. There were considerable pallor and evident leukæmia. The patient died in three or four months. The diagnosis was confirmed and there was central necrosis of some of the glands. The interest of this case rested in its having started with buccal and throat affection It was so very markedly the feature in these cases of acute leukæmia to get stomatitis that it separated some of these cases from others of the same group which were not connected with stomatitis—Dr. PHEAR, in reply, said there had been no purpura in his case at any time. In this case the condition of the mouth was the first symptom, but in some other cases this was not so.

MEDICAL SOCIETY OF LONDON.

A Case of Extensive Enterectomy.—Intestinal Anastomosis for Atony of the Colon.

A MEETING of this society was held on April 22nd, Mr. JOHN H. MORGAN, the President, being in the chair.

Mr. ARTHUR E. J. BARKER read a paper on a case of Extensive Enterectomy. The case illustrated the dangers which sometimes arose as sequels to ordinary strangulated hernia where the bowel in the sac appeared to the naked eye fairly satisfactory and was consequently replaced within the abdominal cavity. The patient was a woman, aged 39 years, who had suffered from symptoms of strangulation in a right femoral hernia for only a few hours. The usual operation was done and a loop of small intestine was found which, though much discoloured, appeared in other respects quite viable. It was washed and replaced in the abdomen and a radical cure followed. Recovery was by primary union and the patient left hospital on the sixteenth day quite well. Soon after she had a violent attack of intestinal obstruction which, under the skilful treatment of her medical man, subsided in due course. Some weeks later, when she had returned to her home in Cornwall, a more violent attack of obstruction took place accompanied by general peritonitis. When this had subsided her medical man sent her up to town again with a view to ascertaining what was the cause of these attacks and whether they were connected with the old strangulated hernia. With this view Mr. Barker agreed and opened the abdomen in the right linea semilunaris. The obstruction was found to be due to kinking of the bowel which had lain in the hernial sac; there was also some shrinkage of the lumen of the bowel at the spot originally constricted in the ring. This shrinking was partly due to ulceration of the mucous coat and partly to inflammatory matter externally to the constriction. The latter was so extreme that nothing but enterectomy offered any hope of remedy. There was extensive matting together of all the adjacent coils of intestine both above and below the narrowing, so that an extensive resection had to be done. The whole mass of matted intestine was resected, amounting to 37 inches, and an end-to end anastomosis was made by suture in the usual manner. The wound was drained with gauze for a few days and then allowed to close. Recovery was uneventful. This case suggested, Mr. Barker thought, that in those instances—which were not uncommon—in which a loop of intestine had been damaged by strangulation, but was to the naked eye far from gangrenous, a wider use might be made of enterectomy than had hitherto been the case. *The risks of returning doubtful* bowel *into the abdomen* were frequently illustrated in practice and were probably greater than a properly planned enterectomy. Mr. Barker for his part recalled many cases in which he regretted not having resected the bowel instead of taking the chance of its recovering its perfect vitality and functions without adhesions. All Mr. Barker's resections of bowel done within the last two years by simple suture had been successful; he had therefore a decided preference for suture rather than for any form of button.—The PRESIDENT remarked that Mr. Barker's case raised the important point of deciding what action should be taken with strangulated bowel and the possibility of resulting constriction and subsequent obstruction. The younger the surgeon the more likely would he be to resect suspicious-looking bowel. Very often very severely damaged bowel would recover and for his part he would hesitate to remove intestine which showed definite signs of vitality. There was danger in removing the bowel in spite of modern methods. The occurrence of stricture after operations for strangulated hernia must be very rare; it certainly was in his experience, and he would be inclined not to resect the bowel if it presented signs of life.—Mr. J D. MALCOLM remarked that this case raised several interesting points. There was no doubt in this case that the bowel was in a condition capable of recovery; and as there was in most such operations a risk of adhesions taking place he questioned the advisability of resection. He had recently operated on a very large inguinal hernia and put back the bowel matted together with a lot of adhesions, and the case did well.—Mr. BARKER, in reply, said that when he examined the loop of intestine after washing it there was not a trace of adhesion, it had not lost its gloss, and the circulation was recovering; but inside there must have been ulceration. It looked a promising case. This patient, however, really ran considerable risks, as shown by the subsequent attacks. It was important to divide the bowel well above and below the diseased portion, and this might be done fearlessly; he had recently removed five and a half feet of intestine from a patient, 76 years of age, with impunity.[1]

Mr. MANSELL MOULLIN read a paper on a case of Obstructive Atony of the Colon treated by Anastomosis The patient was a woman, aged 29 years, who was admitted to hospital in October, 1900 The illness had begun seven years before with attacks of diarrhœa each lasting a few days, separated by intervals of health. At the end of a year the most obstinate constipation set in. There were also severe attacks of "colic" and great pain on defecation. The patient became bedridden and greatly emaciated (weighing only six and a half stones) Purgatives were administered at first with benefit, but in a little while these failed altogether and for the last five years no action of the bowels had taken place excepting after enemata. The last three years had been *spent almost entirely* in hospital. The appendix had been removed, and, in addition to this, laparotomy had been performed on two occasions with the view of obtaining relief from pain. Massage, galvanism, large doses of belladonna, and other remedies were tried without avail. The abdomen was accordingly opened for the fourth time and a lateral anastomosis by direct suture established between the ileum and the sigmoid flexure. The next day the patient passed a liquid motion naturally, the first for five years. Two days later another was passed. The wound healed up without being touched and the patient left the hospital, having put on more than a stone in weight, free from pain, with the bowels acting readily after occasional doses of compound liquorice powder. Mr. Moullin suggested that a similar proceeding might be adopted in cases of intense colitis in which it was thought advisable to give the colon rest in preference to establishing an artificial anus in the cæcal region with all the inconvenience of the constant discharge of liquid fæces. As regards the case which he had brought forward he had quite recently heard that the patient was passing scybala again and the constipation was returning. This pointed to contraction of the anastomotic orifice. Unless this was made of enormous size it was sure to undergo contraction.—The PRESIDENT remarked that the occasion for such operations must be very rare. He would like to ask if any apparatus was used. It would be interesting to know what became of the intervening piece of colon.—Mr. ALBAN DORAN wished to raise the question whether such operations would be justifiable for tympanites. He referred to a case with *great swelling, but the patient suffered no inconvenience* excepting when she "took cold" or suffered from some other trifling derangement of health, then the swelling and discomfort were extreme. He had also met with other cases which were much more serious. Why not resect the intestine in such cases? But it was not the colon which was alone at fault, it was probably a derangement of the sympathetic nerves, and unless the jejunum and sigmoid were anastomosed they would have tympanites still. These very severe cases of tympanites in middle-aged persons were, in his belief, of nerve origin.—Mr. MALCOLM referred to a case resembling the one under consideration. The patient was a woman, 55 years of age, upon whom he had operated several times, removing *the appendix, opening the cæcum,* and removing part of the colon. He proposed to connect the small intestine to the large gut.—Mr. BARKER referred to a case in which he had made a somewhat similar anastomosis to obviate the distress of a fæcal fistula in the right groin which had resulted from an abscess. He "kinked" the intestine, but this was not a success because the fæces continued to pass, as he found at a subsequent operation. He quite concurred in the view that these operations were not so difficult as had been thought. He was of opinion that for cases of chronic colitis transplantation was preferable to right inguinal colotomy.—Mr. MOULLIN, in reply, said that he had united the *ileum to the colon by a double set of* sutures. A lateral anastomosis between the ileum and the colon had a tendency to contract unless made of colossal size. A large proportion of the cases, such as the one he had narrated, were of a neurotic origin, but, nevertheless, surgical intervention was justifiable.

OBSTETRICAL SOCIETY OF LONDON.

Saline Infusion in Puerperal Eclampsia.—Exhibition of Specimens.

A MEETING *of this society was held at 20, Hanover-*square, W., on April 3rd, Dr. PETER HORROCKS, the President, being in the chair.

Dr. ERNEST W. HEY GROVES read a paper on the Pathology and Treatment of Puerperal Eclampsia, with special reference to the use of saline transfusion, with notes of two cases. The first case was that of a primipara, aged 23 years. She had an easy labour in the absence of medical attendance. There were eclamptic convulsions and coma immediately after, which increased in severity for 12 hours in spite of morphia and pilocarpine. Endovenous injection of 100 ounces of hot normal saline was followed by rapid improvement. The coma and convulsions lessened at once and the *fits ceased* within three and a half hours. The coma passed off and diuresis occurred in 13 hours. The second case was that of a secundipara, aged 21 years. Convulsions and coma with anuria ushered in labour at full term. The fits were of extreme violence and numbered about 26 between 2 A.M. and 4 P.M., when 70 ounces of hot normal saline were injected into a vein. The child was born at 6 30 and died almost at once. Frequency and violence of the fits lessened after transfusion, and ceased within 14 hours, while the coma passed off and diuresis was established within 48 hours. The return to consciousness was followed by two days of violent transitory mania and a week after delivery a relapse of the anuria and delirium threatened as the result of a large meat meal. Dr. Groves proceeded to tabulate 47 cases of puerperal eclampsia treated by this method by different observers, chiefly Porak (13) and Jardine (22). These showed a mortality of 12·7 per cent. A summary of the principal facts relating to the pathology and morbid anatomy of eclampsia was given, proving the toxic nature of the disease and showing the essential lesion to consist of minute capillary thrombi with hæmorrhagic infarctions, surrounded by tissue necrosis. This lesion was shown to be of the same character in the brain, the liver, and the kidneys, and to occur also in the lungs, the spleen, and other organs. The greatly increased coagulability of the blood was related to this lesion. The origin of the toxins was considered to be threefold: (1) from the placenta; (2) from the fœtus; and (3) from the alimentary canal. The pre eclamptic stage of the disease was caused by the presence of the toxins in the blood. The actual convulsions and coma resulted when these toxins caused the coagulation of the blood and the multiple capillary thrombi. Dr. Groves concluded by suggesting that the therapeutic action of the saline solutions depended upon its hindering the formation of the capillary thrombi and dissolving those just formed. He pointed out that it could not act primarily as a diuretic because diuresis occurred after the convulsions had ceased. He also referred to cases in which gelatin injections had caused symptoms of anuria and uræmia accompanied by multiple thrombosis, arguing the possibility of these conditions arising from a morbidly increased coagulability of the blood.

---

[1] THE LANCET, page 1186 of present issue.

Dr. HERBERT SPENCER congratulated Dr. Groves upon his interesting paper. He (Dr. Spencer) had only employed saline infusion in two cases, and although both these cases recovered he was far from attributing the result to the saline infusion. The mortality of eclampsia varied greatly. Before the treatment by morphia he had had a long series of successful cases and then several which were fatal. He thought that cases treated by morphia did better than those treated by chloroform, chloral, and bromides, &c., but he had had failures with the morphia treatment too. In his experience, however, morphia lessened the fits more than any other treatment, and as the diminution of the fits lessened the chance of cerebral and hepatic hæmorrhages he thought its value was great, though its employment was not free from danger. In one case, where there was a good deal of œdema of the legs, he had made incisions into the legs and fomented the incisions with a view to aid the elimination of the poison, and as the case recovered he would be inclined to try the effect of the incisions in other cases. With regard to the effect of saline infusions, he had tried their effect in cases of uræmia 12 or 14 years ago without benefit. Dr. Groves had compared the mortality of cases treated by saline infusion with that of cases treated by other methods to the disadvantage of the latter, but it must be remembered that from the former (all modern) cases septicæmia had been in great part eliminated, whereas it caused a considerable part of the deaths of the older statistics. Moreover, there was a tendency to publish successful cases where a new method of treatment was concerned, whereas if the case terminated fatally it was more likely to be unrecorded. One remark in the paper needed correction—namely, the statement that the mortality of cases treated without saline infusion was "never less than 20 per cent." Ebinger had published a series of 28 cases from the woman's clinic at Kiel, 1894–1900, with four deaths, a mortality of 14 per cent. If two cases (one fatal) in which saline infusions were employed were excluded it would be seen that the mortality (11 per cent) was less than that given by the author for cases treated by saline infusion. Dr. Spencer urged that saline subcutaneous infusions should be made with strict aseptic precautions and that large quantities should not be injected at one spot, several cases of local gangrene and even fatal septicæmia having been recorded He was not convinced that saline infusions had lessened the mortality of eclampsia.

Dr. G. E. HERMAN highly appreciated Dr. Groves's scholarly paper. He agreed with Dr. Spencer in thinking that the figures given were not convincing as to the superiority of this treatment. Veit, in his lecture advocating the treatment of eclampsia by morphia, had reported 60 cases with only two deaths; and Charpentier, in a paper advocating treatment by chloral, had collected 239 cases, with a death-rate of only 4 per cent. Here were a larger number of cases and a smaller death-rate than what was now put forward as evidence of the benefit of infusion of saline fluid. The theory put forward was that in eclampsia the coagulability of the blood was increased, but the only evidence of this was that in some cases the medical attendant had been surprised at the small amount of blood lost. Physiologists had, he believed, apparatus for exactly measuring the rate of blood coagulation, and it would be more convincing if the coagulability of the blood in eclampsia had been measured by an instrument of precision. He did not attach importance to the morbid condition said to have been found in the brain and quoted by Dr. Groves. Were the miliary hæmorrhages described by Dr. Groves anything but ecchymoses, such as were seen under the skin, the pleura, and elsewhere, and due to the tremendous venous congestion during the fit? Large cerebral hæmorrhage occurred so seldom that it could not be due to any condition which was a regular and essential part of the disease. He thought that cerebral hæmorrhage was occasionally seen in eclampsia because in a few cases granular kidney and the vascular degeneration associated with it were present, and in such cases the arterio-capillary changes predisposed to cerebral hæmorrhage. Pregnant women with previously diseased kidneys were more liable to eclampsia than those with healthy kidneys. Dr. Groves had described the chronic renal disease of pregnancy under the name of the "pre-eclamptic stage." He (Dr. Herman) thought that this term was hardly appropriate, seeing that not more than one in five of the cases suffered from eclampsia, and that in some cases eclampsia came on without any pre-existing renal disease. He thought the essential morbid condition in eclampsia was the acute degeneration of the cells in the great glands, the liver, and kidneys, and that the hæmorrhages were incidental and a result of the fits.

After some remarks by Dr. C. O. FOWLER and Dr. JAPP SINCLAIR,

Dr. W. S. A. GRIFFITH said he wished, in the first place, to point out the important mistake which Dr. Groves and many other writers on the subject made in discussing this subject under the title of "puerperal eclampsia," the disease being one of far wider extent than this term would indicate, for the cases in which eclampsia occurred were only a small fraction of the total number of cases in which the disease underlying eclampsia—namely, toxæmia with nephritis—was found. It was essential that the disease should be studied in a much wider sense, beginning with the cases in which albuminuria and dropsy in slight degree were the only recognisable symptoms, to the graver cases increasing in severity until even without eclampsia the health, if not the life, of the patient was in great danger, and through these to the cases in which convulsions and coma occurred in varying degrees of severity. Such a method would be of the highest benefit to the practitioner, for it would lead him to a more rational and probably more gentle method of treatment in the urgent cases and to a more rational and more active treatment in the cases which by the absence of eclampsia appeared to be less urgent. Cases of eclampsia and placenta prævia were alike in many ways. They suffered alike from the alarm to which they gave rise and the danger of the methods adopted for their relief. The same principles of treatment applied to both, and while the fact was recognised that the patient's safety was greatly increased by delivery it was forgotten in the hurry and anxiety to carry this out that the means used must be safe and not add to the danger. Forced delivery, morphia, pilocarpine, and septicæmia claimed many victims who ought to have survived if less heroic measures had been adopted. The method advocated by Dr. Groves was quite unnecessary except in a few special cases, but in these it would appear to be of real value by keeping the patient alive until the kidneys and other organs were able to resume their work.

On the motion of Dr. J. W. EDEN, seconded by Dr. A. E. GILES, the discussion was adjourned to the next meeting of the society on Wednesday, May 1st.

The following specimens were exhibited:—

The PRESIDENT: A Uterus from a case of Deciduoma Malignum with Microscopic Sections.

Dr. SPENCER: A Cystic Fibroid removed by Posterior Colotomy.

Dr. H. R. ANDREWS: Kidneys from a fatal case of Puerperal Eclampsia with Microscopical Sections.

The specimens were discussed by Dr. G. F. BLACKER, Dr. VICTOR BONNEY, Dr. HENRY BRIGGS, Dr. GRIFFITH, Dr. HERMAN, Dr. AMAND ROUTH, Dr. JAPP SINCLAIR, and Dr. BELLINGHAM SMITH.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.—Some Practical Observations on Antiseptic Surgery.

A MEETING of this society was held on April 18th, Mr. ALBAN DORAN, Vice-President, being in the chair.

Mr. H. J. CURTIS showed an Infant with Extreme Hemiatrophy of the Head and Face.—The case was discussed by Mr. DORAN, Dr DUNDAS GRANT, Dr. S. G. FELOE, Dr. C S JAFFÉ, Dr. J. M. FINZI, and Mr. J. JACKSON CLARKE.

Mr JACKSON CLARKE showed a case of Contracture of one Rectus Abdominis Muscle causing Spinal Curvature. The patient was a girl, aged nine years. Three months ago he had shown the same patient to the society. At that time there was a marked C-shaped kyphosis affecting the whole spinal column from the skull to the sacrum. The deformity was fixed, not being diminished by the patient's efforts or by passive force. Such fixed deformity had been termed "osseous," but this was not necessarily the case; thus in the present instance the spine had been brought straight by means of an antero-posterior splint and daily exercises. Beyond the straight position in the present instance no further correction could be obtained. This was accounted for by the condition of the left rectus muscle which was shortened and indurated. It recalled the condition of the affected sterno-mastoid muscle in congenital wry-neck. In the present instance no further improvement in the form of the spine, and hence no improvement in the patient's respiratory capacity, could be obtained without lengthening of the affected muscle. This effect would need to be obtained without interrupting the continuity of the muscle.—Mr. DORAN and Dr. DUNDAS GRANT discussed the case.

Mr. JACKSON CLARKE also read a paper entitled Some Practical Observations on Antiseptic Surgery. As applied to surgical work the terms "antiseptic" and "aseptic" were synonymous; whether pathogenic organisms were destroyed by chemical means or by heat it was equally in keeping with the principles of Listerism. Suppuration was to be regarded as a group of closely allied infective diseases. No surgeon or nurse who had any point of suppuration about the hands should take an active part in an operation. Suppurative foci about the patient's skin should also, whenever circumstances allowed, be cured before an operation was done. For preparing the patient's skin or the surgeon's hands for treatment by antiseptic lotion ether soap was to be preferred to turpentine. The soap should be applied to the dry skin and then thoroughly removed by warm water. The surgeon's hands should be kept smooth by the use of glycerine and water after each operation. Where a high-pressure apparatus for the sterilisation of dressings, towels, &c., was not at hand a clean potato-steamer kept briskly boiling for half an hour would answer the purpose. Real sponges formed the best of swabs because they did not leave any of their substance behind in the tissues; they should, however, not be used save when prepared under the surgeon's own supervision. Their proper preparation occupied four days and they should be dried in a dust-proof envelope. Lint swabs wrung out of 1 in 40 carbolic were not sterile; even small portions left behind in a wound caused suppuration. Swabs of absorbent wool inclosed in a double layer of gauze having its cut edge turned inwards were preferable. Mechanical aids to asepsis were never to be neglected. Careful shaving and the thorough removal of loose hairs were imperative wherever visible hair was present on the part to be operated upon. The mechanical removal of grit, &c, from wounds, combined with vigorous douching with warm saline solution, was often preferable to the use of carbolic or other lotions in recent wounds. Silk ligatures might be boiled for five minutes in 1 in 20 carbolic lotion without losing much of their strength; like other ligatures, they should be kept in 1 in 20 carbolic. All drainage-tubes should be boiled before being used. As a dressing in the case of clean wounds Mr. Clarke preferred to apply two layers of cyanide gauze next the skin; over that as much sterilised absorbent wool as was required, and over this again two layers of cyanide gauze. Iodoform was not an antiseptic in the same sense as was carbolic acid or as were the salts of mercury. It should not be applied to clean wounds, but it should be reserved for cases in which complete asepsis was impracticable. A stock of 10 per cent. iodoform-glycerine emulsion should be kept, and in cases in which packing was required sterilised ribbon gauze should be passed through the emulsion well stirred up, and after the surplus had been squeezed out the gauze should be applied to the wound. When saline solution was to be used for intravenous or subcutaneous injection it should be filtered through sterilised white (Swedish) filter paper.—Mr. DORAN had heard numerous discussions on the relative merits of different antiseptic methods as applied to abdominal surgery for over 20 years. Further experience usually proved that the disputants never understood what the term "antiseptic" precisely meant. Wells's "toilet of the peritoneum" was essentially an antiseptic measure, whilst carbolic solutions, though antiseptic, were not disinfectant and thus failed where sepsis was already present. One strong opponent of "Listerism" and "asepsis" used the drainage tube freely, whilst another flushed the peritoneum with hot water, practices designed to remove septic products and therefore coming within the province of the new surgery which they condemned. Long statistical tables of an operation undertaken by one surgeon never proved the value of his method; his experience and dexterity rather than his lotions and dressings produced the good results. Antiseptics could never be soundly advocated by such publications. Mr Clarke had wisely eschewed any recital of his own operative triumphs and had indicated rather how he thought that they should all set to work when they desired to practise true antiseptic surgery.—Mr. HUBERT C. PHILLIPS remarked that Mr. Clarke had made no reference to the after-treatment of wounds—operation or traumatic—by antiseptic dressings, and he called attention to the efficacy of collodion freely painted over strips of cyanide gauze as a means of keeping wounds free from external septic contamination and infection.—Dr. FINZI made a few remarks extolling the value of iodoform as an antiseptic surgical dressing, instancing its value especially in cases of gangrenous ulcers, in operations on the tongue, and as a surgical dressing after circumcision.—Mr. CAMPBELL WILLIAMS, Dr. DUNDAS GRANT, and Mr. H. M. PAGE also took part in the discussion and Mr. JACKSON CLARKE replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Discussion on the Rotunda Hospital Report.

A MEETING of this section was held on March 15th, Dr. A. V MACAN, the President, being in the chair.

Dr W. J SMYLY congratulated the Master of the Rotunda and his assistants upon the excellence of their report, which was creditable not only on account of the brilliant results obtained, but also for the manner in which the work had been recorded. He, however, deplored the classification of abortions as preventable and inevitable, and the absurdity of this classification was demonstrated in the report by the statement that out of a large number of abortions which actually occurred only eight were inevitable. He further objected to the term "induction of abortion" being applied to cases in which sea-tangle tents and tampons were introduced on account of hæmorrhage. In such cases the ovum was already partly detached, and this measure only accelerated a process already begun. Induction of abortion was a very serious procedure, only to be undertaken on the most urgent grounds, and after consultation. With regard to rupture of the uterus he had had good results with iodoform gauze drainage and bad results from operative measures, but in a paper recently published by Dr Klein of Dresden with a careful analysis of 381 cases it appeared that the results were about the same, the mortality after operation being 44 per cent, whilst in those drained, tamponed, or douched it was 39 per cent.

Dr. J. H. R GLENN thought that the report could be very greatly improved. It was full of both typographical and grammatical errors. The cases generally were very incomplete. Case 4, page 2, was most interesting, but there was no diagnosis. In Table IV. there was mention of 13 cases of version—there were several kinds of version, and all through the report he had looked to see if there was any attempt first made at external version, but could see none. He noticed that they had gone back to the old term "transverse" instead of "oblique" presentation. As to the cases of contracted pelvis, he believed, speaking from personal experience, that it took the assistants a considerable time to become adepts in the use of Skutsch's pelvimeter and meantime their measurements were not above reproach. In the table of contracted pelvis there were a great many blanks, a thing which should not be. There was no record kept of the amount of blood lost in cases of accidental hæmorrhage, placenta prævia, or post-partum hæmorrhage. This should be done by weighing diapers and sheets in the hospital. Again it was stated that "three patients who had no hæmorrhage on the couch lost a considerable amount on being put to bed." His explanation of that was the fussiness of sisters and lady superintendents in their anxiety to have the labour ward ready for the next case. He thought that it would be a great improvement if, as in the London hospitals, the report was entrusted to a medical or surgical registrar accustomed to the work year after year. Such a man would produce a more scientific report, and could also do some original work, which was badly wanted in Dublin, where a large amount of valuable clinical material was wasted.

The PRESIDENT agreed with Dr. Glenn that the report contained some extraordinary mistakes. It seemed to be the routine treatment to curette all cases where the temperature went up in the puerperal state, but he did not think it right. He thought 29 cases of manual removal of the placenta a large number. There seemed to be a great many cases of post-partum hæmorrhage. It was stated that "some cases of secondary post-partum hæmorrhage were due to retained membranes, and yielded to suitable treatment." It was many years since he (the President) came to the conclusion that retained membranes could not cause hæmorrhage. In cases of badly contracted uterus both hæmorrhage and retention of membranes occurred, and in removing the latter the insertion of the hand made the uterus contract and stopped the hæmorrhage.

Dr. H. JELLETT, Dr. LANE, and Dr. SMITH also took part in the discussion.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—An ordinary meeting of this society was held at the North-Eastern Hospital for Children on April 19th, Dr. A. Ernest Sansom being in the chair.—Dr. Sansom showed a lad, aged 11 years, many of whose joints were affected with Arthritis Deformans. There were no enlargement of the spleen and no structural affection of the heart. The skin was slightly pigmented. Onset occurred with a subacute attack simulating "rheumatic fever." There was no family history of rheumatism. Great improvement had taken place under massage and measures likely to promote good nutrition.—Mr. R. Clement Lucas suggested that the joint mischief might have originated in a focus of suppuration about the jaws, tonsils, or elsewhere. In a recent case he had found staphylococci in fluid from a hip-joint affected with osteoarthritis. He inquired whether a bacteriological examination had been made in this case.—Dr. Theodore Fisher, Mr. Milner Burgess, and Dr. George Carpenter made remarks.—Dr. Sansom, in reply, said that no focus of suppuration had existed nor was a bacteriological examination carried out.—Dr. James Taylor showed a case of Muscular Atrophy which he believed to be a connecting link between pseudo-hypertrophic paralysis on the one hand and progressive muscular atrophy on the other. In addition to hypertrophy of the muscles there was also considerable wasting. The boy, now aged 10 years, had been under observation for three years and his symptoms had rather improved than become worse. The disease was not symmetrical; there were marked fibrillary twitchings in the affected muscles.—Dr. J. H. Sequeira showed three patients suffering from Progressive Muscular Atrophy. The characteristic phenomena were present. An interesting feature was that although the patients were members of large families yet there was no similar affection in the brothers and sisters.—Dr. Douglas Drew demonstrated three cases of Nævo-Lipoma for Mr. A. B. Roxburgh. The lesions affected the leg and lower part of the thigh in one case, the thigh in a second, and the pectoral, axillary, and intra-spinous regions in the third case.—Dr. Drew also showed a child, aged six years, upon whom he had performed McEwen's Osteotomy for Genu Valgum 12 months ago. The results of the operation were satisfactory in straightening the limb, but although splints had been worn since the operation the latter had failed to cure the dislocation of the patella. Dr. Drew intended to perform a second operation for the dislocation.—Dr. J. Porter Parkinson showed a Gumma in the Heart of an infant, aged three months. The lungs and spleen contained tubercle. The gumma, which lay in the wall of the left ventricle just below the auriculo-ventricular groove, was three-quarters of an inch in diameter and proved to be a pale, tough, yellow mass, well marked off from the adjacent muscle. Mr. Targett reported that the lesion "may be regarded as a gumma of the heart."—Dr Carpenter thought the mass might equally well be one of tubercle. He had published an almost similar case four years ago.—Dr. Fisher regarded the absence of caseation from the specimen as a point in favour of its syphilitic origin.—Dr. Parkinson, in reply, said that the evidence of gumma depended on the hardness of the lesion, the absence of caseation, and the microscopic report.—Dr. Parkinson also exhibited a Perforated Gastric Ulcer in a male child, aged two years.—Dr. Sequeira showed three children with Lupus who had been treated by the Finsen method at the London Hospital. The results had been excellent.—Dr. D. McKenzie showed an infant, aged 11 months, who had been brought up on proprietary food and was now suffering from Scurvy. She had pains and tenderness in the lower limbs and changes in the gums, but no anæmia. There were no signs of rickets.—Mr. J. H. Sanders mentioned a similar case where benefit had followed alteration in diet and the legs being put up in plaster-of-Paris.—Dr. Carpenter mentioned a case where the gums had been treated with chlorate of potash, with the result that the liver became enlarged and the child nearly died.—Dr. Sansom said that chlorate of potash was a dangerous drug owing to its destructive influence on blood corpuscles. Practitioners should think twice before administering it, especially to children.—Dr. Fisher read a paper on a case of Swelling of the Eyelids after a Warm Bath.—Dr. Carpenter and Mr. Sydney Stephenson suggested urticaria as a possible cause.

LIVERPOOL MEDICAL INSTITUTION.—An ordinary meeting of this institution was held on April 11th, Mr. Edgar A. Browne the President, being in the chair.—Dr George G. Hamilton related a case of Enlarged Gall-bladder which was adherent to Poupart's ligament.—Mr. Damer Harrisson read notes of a case of Idiopathic Cortical Hæmorrhage treated successfully by operation.—Dr. Nathan Raw mentioned a case in which he had removed a large tooth-plate from the lower end of the œsophagus by aid of the x rays. The patient, a man aged 35 years, of very powerful physique, was found attempting to cut his throat with a broken tooth-plate; on being discovered he hastily swallowed the plate, pushing it down his throat with his fingers. Examination by x rays revealed it impacted in the œsophagus, just below the level of the upper end of the sternum, at a point (measured with a sound) 12 inches from the teeth and lying transversely across the œsophagus. Repeated attempts with ordinary forceps failed; whereupon the patient was seated in a chair in front of an x-ray tube, the fluorescent screen was held up, and a pair of long forceps were passed down the gullet, being guided to the tooth-plate by carefully watching on the screen. Having obtained a firm hold the plate was dragged out. Some considerable injury must have been done to the gullet by the manipulation, for the patient had an extensive general cellulitis afterwards with great dysphagia, but he made a good recovery and was transferred to Dr. S. A. Gill of Formby for treatment of his mental condition.—Dr. Gill stated that the patient was admitted to his private asylum suffering from ordinary melancholia with suicidal tendencies. There were also external evidences about his throat of recent attempts at suicide and he constantly regurgitated from the œsophagus purulent and very offensive pus; there were also dysphagia, huskiness of voice, and some swelling about the throat. The patient had improved bodily and was now able to take the ordinary diet of the asylum.—Dr. T. B. Grimsdale read notes and showed composite charts giving the mean pulse and temperature curves in two series of cases of abdominal section, comparing the recoveries after antiseptic operations with those after aseptic operations. The ease of the recovery as shown by the pulse and temperature curves, more especially the reduction in the pulse-rate, the absence of pain after operation, and the diminished amount of flatulence, were marked features of the aseptic series. The details of the method adopted were described. The series of 20 consecutive cases consisted of four abdominal hysterectomies, six ovarian tumours (one strangulated and one complicated with abscess of the vermiform appendix), two of hydrosalpinx, one retro peritoneal tumour, three of double pyosalpinx, one ovarian abscess, and three cases of chronic peritonitis with abscess. There was no mortality in either series.—Dr Frank E. Marshall related a series of 52 cases of General Anæsthesia induced with Chloride of Ethyl, for which he claimed the following advantages: the heart and circulation were only slightly affected, the respiratory system was unaffected, the rapid induction of anæsthesia, rapid recovery of consciousness, no bad after-effects, and a longer period of anæsthesia than was produced by nitrous oxide The cases comprised 46 teeth extractions, with two failures; and six minor operations (opening of abscesses and two double tonsillotomies) —Mr. William Fingland thought that nitrous oxide as compared with chloride of ethyl had great possibilities and could be safely prolonged for the performance of many surgical operations Chloride of ethyl inhalation appeared to have many good qualities and its future development as a general anæsthetic would be of interest

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the University College, Dundee, on April 5th, Dr. J. G Havelock, the President, being in the chair.—Dr. J. D Gilruth (Arbroath) gave a short account of some cases of Small-pox and showed a photograph of one of the cases. The relative severity of the symptoms and their relation to the time of vaccination in each case were discussed.—Dr. J. Constable (Leuchars) discussed some cases which he had had in his practice and the supposed origin of the disease in his cases and in Dr. Gilruth's cases—viz, old clothes.—Dr. R. C. Buist suggested the possibility of infection from other ports by ships —Dr. Gilruth replied.—Dr. Gilruth also showed Radiographs of a severe case of Rachitic Curvature of the Tibia and Fibula from which he had removed wedges of bone with good result. Photographs taken before and after operation were also shown —Professor D. MacEwan showed a specimen of Tumour of the Thigh removed from a woman, aged 25 years, the nature of which was as yet undiscovered The history and characters of the tumour did not resemble those of sarcoma or myoma and the tumour itself was quite free from bone There was no history of syphilis —Professor MacEwan also gave an account of three Bladder Cases. The first was a case of recurrent calculi in the bladder. The patient, a man, had been operated on three times Eight calculi were removed at the first operation, two nine months later, and three nine months later than that. Suprapubic lithotomy was performed twice and lateral lithotomy the third time, as the cicatricial contraction resulting from the previous operations had drawn the peritoneum too far down to allow a suprapubic lithotomy to be performed successfully. The second case was one of enlarged prostate treated by double orchectomy with marked improvement. Having had hourly micturition the patient was able four months after operation to retain urine for four hours by day and all traces of cystitis had entirely disappeared Professor MacEwan reiterated the conclusions which he had formed in his paper on this subject read at the meeting of the British Medical Association at Carlisle four years ago and stated that his further experience confirmed these—viz, the diminution of the gland, vesical contractibility might return even after absence of years, and the results were quite as good as those of prostatectomy. These conclusions, he maintained held good if suitable cases were chosen. The indications for this form of treatment were given. Reference was made to the high death-rate on the introduction of this treatment and reasons were given. The mental disturbance after these operations was compared with mental disturbance after operations on other pelvic organs The third case discussed was that of a young man, aged 19 years, who had suffered from frequency of micturition. There was no stricture and no stone but the cystoscope showed an ulcer of the bladder. This ulcer was scraped and the bladder was drained after median cystotomy. Six weeks after the operation the patient was able to retain urine for six hours. This form of complaint was then discussed shortly.—Professor J. A C. Kynoch, Dr. Buist, Dr. Gilruth, and the President discussed several points in the cases —Professor C. R. Marshall then discussed the advantages of heroin and dionin, their composition, and how they had been discovered. Heroin, he said, was similar to morphine in its effects except in one important point—viz, it was less of a depressant on the respiratory system. It was more powerful than codeine but less toxic. Dionin was less powerful than heroin but more so than codeine. The uses and doses of these two substances were then given.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 12th, Dr. Cresswell Baber, the President, being in the chair.—Mr. W. G. Spencer again showed the boy exhibited at the last meeting with a Tumour of the Right Vocal Cord and a Swelling of the Leg Both swellings had greatly improved under treatment by iodide of potassium.—Dr. StClair Thomson showed a man, aged 33 years, with Chronic Laryngitis and an Ulcer on one Vocal Cord which he suggested were secondary to pus in the nose.—Dr. Thomson also showed a case of Infiltration of the Right Vocal Cord in a man, aged 40 years, probably of the nature of pachydermia diffusa, and another case of a similar condition in a man, aged 56 years which he suggested might be due to a blood-clot simulating a neoplasm.—Dr. Scanes Spicer showed a case of Laryngeal Growth occurring on the posterior wall and accompanied by paresis of the left vocal cord which was probably malignant He also showed a case of Sub glottic Swelling of doubtful origin.—Dr Logan Turner showed a specimen of a Larynx from a case of primary laryngeal diphtheria in an adult and one of a Larynx which was studded with small white points of a doubtful nature —Mr W J. Walsham showed a case of Destruction of the Nose caused by a ferret for which 18 operations had been performed —Dr. Jobson Horne showed a case of Epithelioma of the Larynx and Dr. Fitzgerald Powell one of Tuberculosis of the Larynx —Dr. Wyatt Wingrave exhibited specimens of the two chief classes of Intranasal Papillomata, and Mr Lake drawings of (1) a Cyst of the Floor of the Nose and (2) Pachydermia Laryngis of a tuberculous nature —Dr Atwood Thorne showed a case of Pharyngo mycosis the treatment of which was fully discussed —Dr H Tilley showed a case of Antral Suppuration with marked bulging of the inner wall towards the nose.—Dr. L H Pegler showed a case of Cyst of the Thyroid Gland.—In the discussion which followed treatment by means of injection of perchloride of iron was fully entered into —Mr R S Charsley showed a case of Foreign Body in the Nose, Dr Lambert Lack a case of Unusual Tumour on the Posterior Wall of the Larynx, and Dr Dundas Grant (1) a case of Lupus of the Septum, (2) a case of Pachydermia of the Vocal Processes, and (3) a case of Specific Perforation of the Palate with ulceration of the larynx of tuberculous appearance occurring in a woman of middle age.

IPSWICH CLINICAL SOCIETY.—A meeting of this society was held on April 11th, Mr. James Hossack being in the chair.—A vote of condolence was passed to the relatives of the late Dr C M. Durrant upon his demise.—Mr H B. Rygate read notes on a case of Hyperpyrexia in a girl who was admitted to the Fever Hospital suffering from scarlet fever. The temperature rose to 106° F, but was kept down partially by means of ice and sponging. Latterly, before death ensued, the temperature, which was 106°, was unaffected by ice. The patient developed pain and swelling in the right ankle, knee, and shoulder, for which salicylates were given. Mr. Worts showed (for Dr H H Brown): (1) A case of Excision of the Jaw (with specimen); (2) a specimen of Cancer of the Peritoneum; and (3) a case of Gunshot Injury.—Mr. C K Moseley read notes upon, and demonstrated the use of, "Kelene," upon two patients —A discussion afterwards followed the general opinion being that the anæsthetic was unsatisfactory inasmuch as there was great difficulty in knowing when anæsthesia was complete, the patient being in some cases quite conscious though powerless to move.—Mr Hossack showed a specimen of Ascaris Lumbricoides 14 inches long.

SOUTHPORT MEDICAL SOCIETY.—At a meeting of this society, held on April 10th, Dr. Robert Harris being in the chair, Mr. G. Reinhardt Anderson moved the following proposition:—

> That, in view of the difficulty often arising in isolating cases of infectious disease other than those proper for admission to the public infectious hospitals, it is the opinion of this society that steps should be taken to approach the Corporation of Southport and the Local Board of Birkdale, to induce them to provide such accommodation in their new hospitals—under such regulations as would enable individual practitioners to continue in attendance upon their cases; and that a sub committee be appointed to carry out this suggestion.

This was carried unanimously and a sub-committee of eight members was appointed for the purpose.—Dr. W. A. Mackay showed: (1) a Temperature Chart of a protracted case of Enteric Fever; and (2) Pulse Tracings from a case of Mitral Disease with a Tracing of the "Recurrent" or "Return Pulse."—Dr. J. J. Weaver (medical officer of health) read a paper on the "Fourth Disease," and gave details of several cases which had recently occurred in the Borough Hospital either preceding or following typical scarlet fever. Dr. Weaver briefly discussed the symptoms and the diagnosis and an animated discussion followed.

Reviews and Notices of Books.

The Fundamental Data of Modern Pathology. By Dr. ACHILLE MONTI, Professor of Pathological Anatomy, University of Pavia. Translated from the Italian by JOHN JOSEPH EYRE, M.R.C.P. Irel., &c. London: The New Sydenham Society. 1900. Pp. 266.

IN 1897 the Royal Lombard Institute proposed as the subject for a prize essay the following theme: "What influence has the doctrine of proliferation of the cells beyond the normal exercised on the pathology of man? What has that of the pathogenic microbes? Contrast the two doctrines with others older. The advantages of both in the treatment of human infirmities." The prize was gained, very deservedly as we should imagine, by Professor Monti with the dissertation translated in this work, with a few additions, into English.

The subject proposed by the Royal Lombard Institute amounted to an invitation for a critical review of the influence of modern histology and bacteriology upon medical theory and practice. Professor Monti in his brilliant treatise has shown not only a thorough grasp of his subject in its modern developments, but a vast amount of historical learning, together with a critical faculty of no common order. He has strictly adhered to the theme proposed, and his disquisition falls into six chapters in accordance with its terms. In the first he deals with the development and doctrines of "cellular pathology," devoting a good deal of attention to the subject of karyokinesis. He traces the influence of cellular pathology upon the doctrines of inflammation, tumour-formation, and kindred matters. The second chapter treats of the evolution of parasitic theories of disease, of the paths of transmission of infections, and of the modes in which bacteria produce disease. In the two following chapters we find an admirable review of the older doctrines of pathology and of the manner in which they led up to the views held at the present day. The final chapters deal with the practical applications of histology and bacteriology in medicine and surgery, especially in the diagnosis of tumours and of infective conditions. The writer also treats of the questions of antiseptics, preventive inoculations, and serotherapy.

There is so much that is admirable in the essay that it is not easy to pick out any special parts for criticism. But we should like to call attention to the apparently in some cases well-founded claims made by Professor Monti as to the priority of certain observers, commonly overlooked, in the credit of establishing or suggesting doctrines now universally accepted. Bottini is stated to have anticipated Lister in the use of carbolic acid in surgery and to have proclaimed the doctrine of antisepsis a year before Lister's first publication on the subject. The theory which attributes the origin of neoplasms to included embryonic rudiments, usually known as Cohnheim's theory, appears to have been previously developed in some detail by Durante. The doctrine of pathogenic micro-organisms in its modern sense was first laid down by Bassi in 1835. Pacini described vibrios in Asiatic cholera in 1854 These facts do not detract in any way from the credit of those whose labours afterwards established the doctrines in question on a firmer basis, but they are of great historical interest, and Professor Monti gives chapter and verse for them all and for many more. It is pleasant, too, to find full credit given to William Addison and to Waller for their shares in the development of the doctrine of inflammation. The writer seems, indeed, more familiar with the older school of English pathology than with the labours of our more recent workers. A very important section of the last chapter, largely re-written since the work was first produced, is that relating to malaria. It constitutes one of the best accounts of the life-history of the malarial parasite and of the mosquito theory accessible to English readers. We are not in agreement with Professor Monti on every point with which he deals; notably we cannot agree with his views on the simplicity of the bacteriological diagnosis of diphtheria. The book is one, however, which will be read with pleasure and profit by everyone interested in pathology and it constitutes a brilliant addition to the critical literature of the science. We regret to add, in conclusion, that the pleasure of the reader is sadly marred by the character of the translation, upon which the new Sydenham Society can by no means be congratulated. The genius of the Italian language differs so widely from that of the English tongue that any attempt to turn the one into the other without a considerable recasting of the sentences can only end in disaster. Every page of this translation is disfigured by sentences which hardly deserve the name of English. The definite article is habitually inserted where it is not needed; words are frequently used in their wrong order and not rarely in their wrong sense. Thus the translator often writes "successive" where he means "succeeding" and "distended." where he means "spread"; on one page we even find "incommensurable" used for "innumerable." The result is often nonsense. He is addicted, too, to the use of barbarous words, such as "neoformed" and "laparotomic," and his classics are as bad as his English. Thus he coins the words "nephrites," "peritonites," &c., as plurals of nephritis, peritonitis, &c. We read of "bacillus tetanis" and learn that "Natura non facit saltus." Much of this may be pure carelessness, and, indeed, misprints are not uncommon, especially in the footnotes, but the reputation of the New Sydenham Society is too high to allow us to pass over in silence so slovenly a translation of a work of signal merit.

Diphtherie. By Professor Dr. E. v. BEHRING. Berlin: Verlag von August Hirschwald. 1901. Pp. 200. Price 5 marks.

THIS book forms one of the series belonging to the "Bibliothek von Coler" (Coler's Library), edited by Dr. Otto Schjerning, an officer holding one of the highest positions in the medical department of the German army. The works appearing under his editorship naturally, therefore, have special reference to military medicine.

This volume contains a very complete account of diphtheria from every point of view. Some interesting information is to be found under the heading "Begriffs-definitionen." This term includes not simply a "definition" of the word "diphtheria," but also a history of the synonyms which have been employed and a consideration of the confusion that at one time existed between the signification of the terms "diphtheria" and "croup."

The name of the author is sufficient to indicate that the sections on the bacteriology of the disease would be most instructive. Nor will the reader be disappointed. A detailed account of the characteristics of the Klebs-Löffler bacillus is given, including many original experiments conducted by Professor Behring himself. The bacteriological diagnosis receives due attention, but the questions of artificial immunity and serum therapeutics scarcely receive the attention due to them.

Leitfaden für Operationen am Gehörorgan. (*Guide to Operations on the Organs of Hearing.*) By Professor Dr. F. TRAUTMANN, Geh. Med.-Rath, Generalarzt a. D., dirig. Arzt der Abtheilung für Ohrenkranke in der Königl. Charité. Berlin: Verlag von August Hirschwald. 1901. Pp. 120. Price 4 marks.

THIS book forms the fourth volume of the "Bibliothek von Coler." An account is given of the most important operations on the outer ear, including the removal of tumours, benign and malignant. Directions are also given as to the various operations which may have to be performed on the inner ear, such as paracentesis of the membrana tympani, tenotomy of the smaller muscles, removal of the ossicles, &c. The directions are given in simple language and should be not difficult to follow. The value of the little work is considerably increased by the 27 illustrations which appear in the text.

LIBRARY TABLE.

Practical Points in Nursing for Nurses in Private Practice. By EMILY A. M. STONEY. Second edition. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 456. Price 7s. 6d. net.—We find some difficulty in reviewing this book, for it is evidently written with every desire that it should be of use to those for whom it is composed, and yet it bears evidence in many places of haste and carelessness. Let us first give such praise as is due. The purely nursing portions of the book are good, and the instructions given in Chapters I., II., and III. are very practical; so is Chapter V. on Nursing in Special Medical Diseases, more especially the section on caring for the dead, which is admirable. But when Miss Stoney strays into the paths of medicine or pathology or the kindred sciences she goes somewhat astray. Thus under the head of "Irritant Poisons" we find ammonium given, and as antidotes for it vinegar, lemon juice, and the like. In the next line we find ammonia given separately together with the other caustic alkalies. On p. 263, under the head of "Dressing the Cord," we find that the cord should be "placed on the left side of the body, because if placed on the right side it would press upon the liver, which at birth is larger than the other organs and which reaches down to the navel." It is absurd to suppose that two inches of cord would press upon the liver to any harmful extent, and the liver, whether in the infant or in the adult, is always larger "than the other organs," although in the infant it is larger in proportion than in the adult. Miss Stoney's style lacks clearness. Take the following (p. 165) *Apropos* of hysterectomy she says: "Insanity is *not* a complication of this operation, the recovery from which is usually rapid, but when insanity does set in this is commonly the cause, and the patient generally recovers." On reading this sentence we could not at first understand to what "this" in the clause "this is commonly the cause" referred, but on looking at the commencement of the paragraph before the one which we have quoted we found that Miss Stoney was referring to loss of blood and shock. Miss Stoney in her preface thanks a certain medical man for his "technical revision and for other kind assistance." We would suggest that before the third edition appears he, or someone else, should revise the text again.

Lehrbuch der Wochenbettpflegerinnen. (*Manual for Monthly Nurses.*) By Dr. PAUL RISSMANN. With Nine Illustrations. Berlin: Karger. 1901. Pp 66. Price 1 mark 60 pfennig.—This little book is intended as a manual of instruction for monthly nurses. It contains a considerable amount of information put in a concise and clear manner. The author has taken care not only to give the most important facts about pregnancy, labour, and childbed, but has also added short paragraphs upon elementary subjects, such as weights and measures, percentages, and the method of using and reading a thermometer. The various complications that may arise either during labour or childbed are mentioned, as well as the more important disorders of the newly-born infant. As the various subjects are arranged in numbered paragraphs and a fairly full index is added reference to any particular point is easy. The information given is well within the grasp of a fairly intelligent woman and cannot fail to be of service to such German women as are engaged in this branch of nursing. The book is interleaved so that notes can be made.

How to Nurse the Sick. (The Home Series.) Edited by FLORENCE WHITE. Pp 84. With numerous Illustrations. London: *Black and White* Office. Price 2d.—This is a very useful little book of instruction intended for that large class of persons who in times of sickness are most likely to have neither a trained nurse at home nor hospital treatment. By carefully following the precepts here laid down any woman of average intelligence should be able to render herself of far more assistance to the medical man than she would be if entirely uninstructed. The general indications for hygiene, cleanliness, and preventing the spread of disease are stated with most commendable simplicity and clearness. A useful form of chart for the home nurse to fill in daily is contained in the book and at the end is some judicious advice for the treatment of such slight ailments as do not necessitate the aid of a medical practitioner. Care has been taken, however, nowhere to encroach beyond the nurse's province and readers of the book are more likely than are the ignorant to seek medical aid at the proper time. A copy of this little work placed in the hands of the wife or sister who is acting as nurse would often save a medical man time and trouble where there is no trained attendant.

The Coming Waterloo. By Captain CAIRNES. London: Archibald Constable and Co. 1901. Pp. 364.—In this volume is given an account of an imaginary war between England and France. At the commencement of the narrative it is supposed that a naval war has been in progress for some time, but has come to such a pass that it appears to be impossible to exhaust either of the combatants sufficiently to compel him to sue for peace. At last comes a change: Russia draws the sword on behalf of France, and Germany and Austria become allies of Great Britain. The story relates the experiences of a certain Lieutenant Walter Desmond of the Royal Ulster Fusiliers. The English army is landed in France and the supposed engagements which follow are graphically described. In the end the French are driven back and, history repeating itself, the Germans arrive in time to complete the rout. The book is written in an interesting manner, but not being military authorities we cannot comment on the tactical and other special knowledge exhibited. A thrilling account is given of an engagement fought under the rays of powerful electric lights, but the chief point insisted on is the value of training the men to shoot accurately and with judgment. It is shown how with such qualities "the highly-trained few will annihilate the half-trained multitude in the fighting of the future."

The Psychology of Reasoning based on Experimental Researches in Hypnotism. By ALFRED BINET, Doctor of Science, Laureate of the Institute (Académie des Sciences and Académie des Sciences Normales), Director of the Laboratory of Physiological Psychology in the Sorbonne (Hautes Études). Translated from the Second French Edition by ADAM GOWAN WHYTE, B.Sc. Chicago: The Open Court Publishing Company. London: Kegan Paul, Trench, Trübner, and Co. 1901. Pp. 192. Paper covers. Price 1*s.* 6*d.*—This book is, we notice, the forty-seventh of a series published under the general title of "The Religion of Science Library" and is "entered at the Chicago Post Office as second-class mail matter." We do not profess to be able to explain the exact significance of the expression "second-class mail matter," as understood at the Chicago Post Office, but possibly the information may be of use to some of our readers. It is not quite clear for whom the translation of M. Binet's book was made. To anyone generally familiar with the writings of Carpenter, Herbert Spencer, Maudsley, and Hack Tuke, and who has a practical knowledge of the proceedings of the Society of Psychical Research, the book may be recommended as a good one to while away the time spent in a long railway journey. To those who wish to obtain information on the psychology of reasoning we should recommend a previous study of the works of the authors whom we have mentioned. M. Binet, like so many of the modern French school of psychologists, attaches to researches in hypnotism an importance to which they are not entitled. He is presumably a serious person, yet we notice amongst other works on psychology issued by the publishers of this book one entitled "The Psychic Life of Micro-organisms," written by the same author.

Practical Licensing Reform. By the Hon. SIDNEY PEEL, Barrister-at-Law, late Fellow of Trinity College, Oxford, Secretary to the Royal Commission on Liquor Licensing Laws. London: Methuen and Co. 1901. Pp. 144. Price 1*s.* 6*d.*—This is an extremely good little book, on a most important subject, written by a clear-headed, well-trained, earnest man who has had a unique opportunity of obtaining accurate information. It is, perhaps, hardly necessary for us to say that Mr. Peel is a son of the late Speaker of the House of Commons, and that as secretary to the late Royal Commission on the Licensing Laws he necessarily had brought to his notice all the evidence given before that Commission. It may, however, be well to point out that the secretary of a Royal Commission during the whole course of the sittings is daily and hourly brought into personal contact with the witnesses who are examined, and by this means he obtains a clear insight into the whole trend of the question under review, of the personal idiosyncrasies of the individual witnesses and of the peculiarities of the interests which they represent. For these reasons we heartily commend this book to all those who are interested in the question of the licensing laws—that is to say, to all those who have at heart the well-being of the people of Great Britain and of Ireland. The book gives an account of the licensing laws as they exist at present and contains chapters on the excessive number of licensed houses and its effects and on the tied-house system. The causes of failure in the present licensing administration are dealt with under the headings: (1) Defects in the Law; (2) Defects in the Licensing Authority; and (3) Defects in the Results of Appeal to Quarter Sessions. The attitude and administration of the police and police authorities are dealt with in a separate chapter. The effects of Sunday closing and the questions connected with the *bonâ-fide* traveller and with clubs are dealt with in detail. There are a chapter on the popular control of the liquor traffic and an appendix containing a summary of the recommendations of the Royal Commission. Every subject is carefully, concisely, and conscientiously treated. We cannot deal in this place with the complicated questions raised. We do not profess to be in exact accord with Mr. Peel on every point with regard to which he gives an opinion, but on all matters of fact the book may, we believe, be absolutely relied upon, and for this reason, as well as for others previously given, we trust that the book will have—as it certainly deserves to have—a wide circle of readers.

La Grossesse. By Dr. L. BOUCHACOURT. With a Preface by Professor BUDIN. Paris: Georges Carré et C. Naud. 1901. Pp. 516.—Though doubtless very carefully prepared and valuable in its way this work will probably not find many readers among the profession in England. The book contains physiological studies of the pregnant state in women and the lower animals; a review of both ancient and modern opinions bearing on the influence of every-day occurrences on that condition; and, lastly, remarks on the attitude of French public opinion towards unmarried pregnant women and comments on the institutions and associations existing for their benefit and assistance. In the earlier chapters, though mentioning sexual excitement, hot baths, horse-riding, bicycling, sea-voyaging, and railway travelling as possible and fairly frequent causes of abortion, the author makes no reference to the very numerous midwives in France who are really abortion-mongers and who ply their trade with little risk to themselves. Dr. Bouchacourt grieves greatly that so little is being done to combat the growing relative depopulation of France and urges that for the sake of the State every care ought to be taken of women who become pregnant. As things are, a poor woman who is *enceinte* probably finds her way to Paris or other large town and having been delivered there at the maternity charity elects to remain in the city rather than to face her people at home. At the present time idiots, cretins, deaf-mutes, degenerates, and epileptics are better looked after by the State than are the mothers of the future soldiers and citizens of France. The Academy of Medicine in 1891 recommended that an asylum for pregnant women should be built at the public cost in every department of France. In 1892 the Conseil Supérieur de l'Assistance Publique passed a resolution to the same effect. Up to the present time no steps have been taken in the matter by any of the public bodies, but an enterprising architect named M. Legriel has designed plans for maternity asylums and sanatoria which will be found at the end of the book. The descriptions of the plates are in the last few pages of the letterpress.

Annuaire des Eaux Minérales. By Dr. G. MORICE. Forty-third year. Paris: Librairie Maloine. 1901. Pp. 338. Price 1 fr. 50 c.—The editor of this handy little guide is the editor-in-chief of the *Gazette des Eaux*, and he thoroughly understands how much is wanted in a guide such as this one. There are the names of the members of the Public Health Committee, a long catalogue of spas and hydropathic establishments with their medical officers, an alphabetical list naming the physicians in France who engage in hydropathic work, a classification of the French mineral waters, and the French sanatoria for phthisis are also given. Under the name of each spa are given various particulars: the altitude in metres, brief descriptions of the chemical type of the mineral waters, the indications for their use, and details of travel to the place from Paris by rail. Most of the principal spas of foreign countries are also given, with a few particulars in each case. The British watering-places referred to are those of Bath, Buxton, Harrogate, Cheltenham, Leamington, Malvern, Matlock, Perth, and Tunbridge Wells. The guide should find a place on the study-table of every physician who prescribes hydro-therapeutic measures to his patients.

The Chronicle of a Cornish Garden. By HARRY ROBERTS. London: John Lane. Pp. 190. Price 5*s.*—Mr. Harry

Roberts, who is, though he does not say so on his title page, a medical man, has written a very charming book. He knows what a garden should be and has apparently made a pleasaunce out of most unpromising material; so his book is full of comfort for those who may hope to spend their later days in possession of a garden, however humble. Mr. Roberts gardens in the true spirit of a gardener, that spirit, we mean, which filled Campion and Marvell when they wrote about gardens and flowers—the spirit which makes a man look upon a garden as a retreat from care, as a companion, and as a source of pleasurable anticipation—an anticipation which is sometimes fulfilled despite the pessimism of that delightful little book "My Summer in a Garden." Given the opportunity, and there is no pleasure so cheap, so lasting, and so enjoyable as a garden We should add that Mr Roberts modestly refuses to illustrate his book with pictures of his own garden but instead supplies pictures of an ideal garden by F. L. B. Briggs.

On the Sterilisation of Milk: Its Advantages and Limitations. By A. D. BLACKADER, M.D., M.R C.S Eng. Pp. 12.—In this pamphlet, which is a reprint from the *New York Medical Journal* of Feb 2nd, 1901, Dr. Blackader, Professor of Pharmacology and Therapeutics in McGill University, Montreal, strongly advocates the pasteurisation of cow's milk for infant feeding at a temperature not exceeding 60° C. (140° F.). He quotes various observers to the effect that at this temperature in closed vessels (but not in open vessels) 99 per cent of all the bacteria present in milk are destroyed. At 70° C. (158° F.) milk acquires a more or less scalded taste and undoubtedly undergoes some chemical changes, probably the following: (1) its proteids are modified and rendered apparently less digestible; (2) the salts assume a condition in which they are less readily absorbed; and (3) natural ferments, the presence of which in milk may with much probability be inferred, are destroyed.

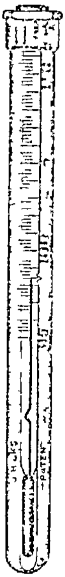
Cholecystitis complicating Typhoid Fever. By W. F. HAMILTON, M D. Pp 5—In this pamphlet, reprinted from the *Montreal Medical Journal* for December, 1900, Dr. W. F. Hamilton, Lecturer in Medicine, McGill University, describes four cases of cholecystitis complicating typhoid fever occurring during 1900 in the wards of the Royal Victoria Hospital, Montreal In three of them the first symptoms of cholecystitis showed themselves on the twenty-eighth, twenty-ninth, and thirtieth days of the disease, but in the fourth case on the seventy-second day. In two of them the abdomen was opened and the gall-bladder was found to contain calculi and to be necrosed in places; in the other two cases no operation was performed All the patients recovered.

Sidmouth as a Health Resort. By A MACINDOE, M D Glasg., D.P.H. Bristol: John Wright and Co 1900. Pp 68 Price 1s.—The reviewer who is experienced in the class of book a specimen of which is now before us, is struck by the fact that any given watering place or health resort is superior to any other, if not in every way at least in most. Dr. Macindoe has, however, with rare self restraint tried to show what Sidmouth is, and not to suggest what other places are not. Sidmouth is without doubt a very pleasant place and has the advantage of not being fashionable, in the sense that it is not haunted by the tripper It is warm and sunny, well-drained, and has a good water supply, and the reports of the county medical officer of health which are quoted by Dr. Macindoe show that the death-rate is low and that the sanitary policy of the authorities is very advanced. The sewerage of the town was almost entirely renewed at an expenditure of about £10,000 in 1897. To those who wish to read a clear account of a clean little town situated in the midst of beautiful scenery, Dr. Macindoe's *brochure* may be recommended.

New Inventions.

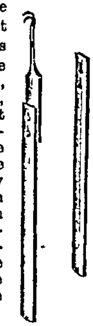
A HYGIENIC CLINICAL THERMOMETER.

THIS is a new departure in the form of clinical thermometer. The scale is not cut in the thermometer itself but in a glass case, which replaces the usual metal one. This renders the surface perfectly smooth so that it can be readily cleaned—undoubtedly a great gain. This advantage is somewhat detracted from by the trouble which is experienced by always having to replace the thermometer in the case before the temperature registered can be read off. The thermometer is made by Mr. Hicks of Hatton-garden, London, E C



A SIMPLE SELF-RETAINING UTERINE TENACULUM.

A UTERINE tenaculum is indispensable to the gynæcologist, but the holding of the same unfortunately monopolises the use of one hand completely Having (no doubt with many others) experienced this inconvenience I have devised a simple plan of getting over the difficulty, and Messrs Reynolds and Branson, Limited, of Leeds, have carried out the idea satisfactorily. The illustration represents the instrument, the greater part of the handle being made of flexible metal, which can be easily bent round either the pubes or sacrum after the necessary downward traction on the cervix has been made, assisting materially in the bimanual examination of the uterus and also the palpation of the posterior wall of the same through the rectum. The value of the tenaculum will be most appreciated in private practice where an assistant is not often to be had. If used through an ordinary cylindrical speculum it will not only hold the cervix but render the speculum self retaining in addition.



Cheltenham. ALEXANDER DUKE, F.R C P. Irel.

HEALTH OF CHARD.—Mr. G. Barnes, the medical officer of health of Chard, in his annual report for 1900 states that the population of the town is estimated at 4500, with an area of 403 acres. The birth-rate was 26 8 per 1000 and the death-rate was 17 7 per 1000. Among infants under one year there were 22 deaths, giving a death-rate of 178 8 per 1000 children born.

THE HOSPITAL SATURDAY FUND.—The report of the council of this fund for 1900 is a satisfactory one It shows that the total income was £20,280, being £267 in excess of the income for 1899 and £142 more than the amount collected in 1897, the last year when there was a street collection on behalf of the fund The total sum distributed was £17 698 This amount has only been exceeded twice in the history of the fund—viz, in 1893 and 1896, when [illegible]

and miscellaneous institutions received £6209. The total number of patients sent to convalescent homes was 1165; of this number 812 were sent with free letters and 353 paid £354 towards the cost of their maintenance. The number of surgical appliances supplied was 3115, the cost being £2558; of this sum the recipients paid £1377. The expenses of management amounted to £2277. This sum is at the rate of 11 23 per cent, the lowest rate recorded with the exception of that for the preceding year, when it was 10 95.

THE LANCET.

LONDON: SATURDAY, APRIL 27, 1901.

The International Organisation of Science.

IN the past history of the world, and not so very long past, it could hardly be said that science knew no nationality, for political conditions worked so strongly to the disadvantage even of minds bent on unravelling scientific truths that no interchange of knowledge was possible. But fortunately now for the interests of science all this is being changed. The tendency among the scientific to sink all differences of nationality, creed, or race, and to cultivate a spirit of cosmopolitanism is recognised as natural. A spirit of scientific commonage is growing up amongst us which should make finally for peace and concord. One undoubted means towards the advancement of international scientific coöperation would be the publication of an international catalogue of scientific literature under the control of the civilised world's learned societies, and this step has been proposed and, moreover, is likely to be realised. Scientific literature has already done much to make science international by encouraging investigators of different nationality to work in harmonious relation with each other. But much as it has done literature cannot do all. What is wanted is an organisation the aim of which shall be international coöperation in all practical affairs that pertain to the pursuit of the truth; that shall promote an exchange of ideas as to the lines on which research will yield the most satisfactory results; and that shall influence the methods of scientific training. Such a movement would render science and civilisation a service of which it would be impossible to exaggerate the importance. The need for international cooperation in the study of the foundations of knowledge has long been felt, and it is satisfactory that we seem to be within measurable distance of the formation of the nucleus of such an organisation. An International Association of Learned Societies has now made a fair and promising start, and that the movement will bear fruit of the most important and cosmopolitan kind there is little doubt. Such a body is calculated to draw to its conferences not only the leading thinkers of the scientific world but the minds of the diplomatic and economical worlds also.

Last week the first Congress of the International Association of Learned Societies met in Paris under the presidency of M. DARBOUX, the permanent secretary of the Paris Academy of Sciences, and there were present a group of famous men as representatives of science in Austria, Belgium, Denmark, England, France, Germany, Holland, Hungary, Italy, Russia, and Sweden—men who have revealed to the world some of the most marvellous secrets of nature. Thus there were in conference together in Paris such famous persons as M. BERTHELOT, M. MOISSAN, Sir MICHAEL FOSTER, Professor E. RAY LANKESTER, Sir ARCHIBALD GEIKIE, Sir NORMAN LOCKYER, Professor RÜCKER, Signor CANNIZZARO (the celebrated Italian chemist), Signor MOSSO, Dr. VAN'T HOFF (whose magnificent contributions to our knowledge of the nature of solution and the constitution of matter are so widely known), and Professor A. FISCHER (of Leipsic, the well-known botanist). The chief object of this conference of *savants* was, in the words of M. DARBOUX, that the man of science devoting his life to the most delicate or the most abstract researches may cease to feel himself isolated while still preserving that independence which is the greatest good and the primary need for the honest investigator. M. DARBOUX eloquently pointed out the splendour of the work that an international organisation of science could do by uniting in the different academies all those who are studying the same subject; by giving them, if they wish it, the opportunity of joining in a common work; by drawing the attention of different Governments to all the schemes the speedy realisation of which is necessary or desirable; and by indicating to Governments the means of executing these schemes in the most favourable conditions and with the greatest possible saving. If the great thinkers of the world can through the association get into touch with the people the association is destined to become rapidly one of the most powerful instruments of concord and of progress.

It is in the irony of things that the International Peace Conference at The Hague was shortly followed by one of the biggest wars into which this country has been plunged. And it may be that the international organisation of science will at first bring about a result diametrically opposite to that which had been hoped. Science tends to increase the ingenuity of fraudulent practices while it provides machinery for the maintenance of a higher standard of probity. It opens up greater possibilities of peace, yet at the same time it provides powers for the wholesale destruction of human life. Nitrogen is the most important constituent of our food and at the same time it is the essential element in the high explosive. Mr. NOBEL was probably the most prominent manufacturer and inventor of explosives that the world has seen and he acquired a massive fortune from his inventions. He left his great wealth to be distributed to those who could suggest the scheme that was best calculated to promote the peace of nations and the prevention of warfare, realising the strange paradox to which we have drawn attention. It is our conviction that science will ultimately triumph in bringing about the peace of the world, though there may be many centuries to wait for this consummation. And because this conviction is widespread among thoughtful people an annual international conference of scientific men has a deeper significance than at first sight would appear.

* * *

"Some Fallacies of Therapeutics."

UNDER the above title Dr. GEORGE L. PEABODY of New York has recently delivered an address to the Practitioners Society, which has been published in the *Medical Record* of New York and which we have read with much interest. Dr. PEABODY does not exaggerate when he says that in these days we are in danger of being swamped by the multiplicity of devices to cure the ills of man. New remedies and new preparations of old remedies are devised in such profusion that the practitioner is tempted to make a constant succession of experiments on his patients and to take short cuts to cure diseases, in many of which there is an element of regularity and of time which cannot be ignored with impunity. Dr. PEABODY adduces several instances of what he considers the persistence of exploded ideas of the action of medicines. He even goes so far as to say that the latest editions of works on therapeutics are full of echoes of the past, repeating the errors and inconsistencies of the old editions and the older writers from a spirit of conservatism or inertia, as if we had no more accurate means of investigation to-day than our forefathers had generations ago. Certain illustrations which he gives of this tendency are worth quoting, but a cursory glance at some of the works of our later therapeutists which happen to be before us scarcely satisfies us that Dr. PEABODY is justified in his general censure.

Dr PEABODY alludes to the use of bitters as appetisers as an example of traditional error. "Perhaps no idea in therapeutics," he says, "is more widespread or more generally acted upon than that bitter substances conduce to an improvement in the appetite, and certainly none is less susceptible of explanation or proof." He denies that the effect is due to the contact of the bitter substance with the mucous membrane of the stomach, and attributes it rather to a stimulation of the sense of taste leading to flow of saliva, which is known to excite the secretion of gastric juice This view of the indirect action of bitters as appetisers through the increase of the salivary secretion is brought out in all the recent works to which we have referred. Dr PEABODY also points out that in the vast majority of cases in which bitters are taken to increase appetite they are mixed with alcohol in some form, as in "the cocktail," in the class of "tonics and bitters," and in other seductive drinks, almost always, he says, sold as being non-alcoholic, but which are found upon examination to contain a large amount of alcohol. The Board of Massachusetts a few years ago found that of 47 of these preparations examined 46 contained more than 21 per cent of alcohol. A preparation called "sulphur bitters" contained no sulphur and over 21 per cent. of alcohol, and one dealer's "sherry wine" bitters yielded 47 per cent of alcohol. No doubt the action of such quantities of alcohol by irritating the mucous membrane might temporarily increase the appetite and stimulate the flow of gastric juice, but no physician would approve such "medicines" or expect anything but permanent mischief from them. Loss of appetite is due to a great variety of causes and is to be met by an equal variety of remedies, amongst which the mere administration of bitters we should regard as the least important and the most doubtful. It is generally due to some defect of health or some neglect of hygiene or some error of habit which the true physician will take trouble to find out In detecting and explaining such a cause he will do his patient the greatest possible service. But certainly the mere administration of a bitter to a patient suffering from loss of appetite will often be the worst possible treatment. Another illustration given by Dr. PEABODY of the survival of false notions among the laity, and even sometimes among their professional advisers, is with regard to the action of alcohol. He finds both among medical men and their patients a lack of due recognition of the injurious action of alcohol on "the heart, arteries, and tissues generally" of persons who have the reputation of never having been drunk in their lives

"Investigation of such cases has often shown that the patient has been a steady and persistent and even hard drinker who always drank more alcohol than he could possibly oxidise, whose heart, arteries, stomach, liver, kidneys, and brain all showed evidence of degenerative changes directly due to alcohol, the victim himself and his friends honestly believing that the limits of temperance had never been overstepped because he never got drunk. It is not surprising that this should be the lay measure of the possible evils of alcohol, but that doctors should share such a belief and sanction indulgence in spirits accordingly, is truly deplorable."

Dr. PEABODY, in further illustration of what he considers to be the survival of errors in therapeutics, refers to the question of the efficacy of creasote and boric acid as germicides, of calomel as a stimulant of the liver, of lithium as a solvent of uric acid, of iodide of potassium as an effective eliminant in lead poisoning, and of the too indiscriminate use of the inhalation of oxygen. While admitting that he sounds a needed caution to medical men, and even to writers on materia medica, not to be too much bound to old beliefs, we think that he scarcely allows sufficient credit to observers for discrimination and advance in therapeutic reasoning. The fact is that we have not yet sufficient material for a system of therapeutics based on strictly scientific principles The medical practitioner, while deeply sensible of his obligations to those who in a spirit of research study the action of drugs and of their active principles, has to act in the emergencies of disease according to his own lights He cannot and does not expect to find in any manual of therapeutics a compendium of medical dicta by following which his personal responsibility for the treatment of his patient would be lessened. But he is most anxious for therapeutical suggestions, based. not upon tradition, but upon the collated results of medical practice This is what Dr. PEABODY thinks he is not properly supplied with.

* * *

The South African Honours Gazette.

THE long-expected *Gazette* of honours and promotions for services in the South African war has made its appearance. It is probably the longest *Gazette* ever published, but it nevertheless only extends to the time when Lord ROBERTS handed over his command to Lord KITCHENER, to whose lot it has fallen, at an extremely difficult and arduous phase of the campaign, to conduct affairs to a successful issue. Lord KITCHENER will then have his own recommendations to make regarding the honours and distinctions which have still to be given, so that an obvious opportunity will soon occur for the rectifying of omissions. Appointments to the Order of the Bath, the Order of Saint Michael and Saint George, and the Distinguished Service Order fill sixteen and a half columns of the *Gazette*, and the promotions fill seven and a half, while there is an appendix of five more. It can be claimed as a whole for the latest award of honours and distinctions that these have been freely bestowed. So large an army has been engaged for so long a time over so huge an area that it is impossible that all exceptionally good work wherever done can have received recognition. Legitimate disappointment will undoubtedly be felt in some quarters, but with one notable exception the *Gazette* is a generous one. The exception leaps to the eyes. The name of the head of the Army Medical Service is conspicuous by its absence. As if to accentuate the fact we find that Sir HENRY BRACKENBURY and Sir C. MANSFIELD CLARKE, the Director-General of Ordnance and the Quartermaster-General respectively, receive the Grand Cross of the Bath. We are at a loss to conceive how the omission is to be explained. The Director-General made every provision in his power for the hospital service in South Africa. It was no possible fault of his that the war attained the magnitude that it did and assumed a character which neither the military authorities nor the nation, indeed, foresaw it would assume. He did not fail to point out beforehand any shortcomings that existed, and the Royal Commissioners in their report expressly acquit him and the staff of officers associated with him of all blame in the matter. We are consequently, as we have already said, entirely at a loss to understand the omission of his name from the *Gazette* and fail to see any justification for it. Even apart from all other and higher considerations the unwisdom of such partiality at the present time must be obvious, and it is, in our opinion, greatly to be deplored in the interests of the army and of the State. It can hardly be expected that the Royal Army Medical Corps will be other than an unpopular service when its officers and the medical profession see the representative head of it studiously ignored in so marked a way. Speaking generally, the Army Medical Service and its officers in the field, and those who have been connected or who have done duty with it in South Africa, have, we are glad to notice, had their services recognised. It is needless to repeat here all the names, which will be found in another column, but we may select for special notice those of Captain NICKERSON, R.A.M.C., and Captain INKSON, R.A.M.C., who, as previously chronicled in our columns, have received the Victoria Cross, making with Lieutenant-Colonel BABTIE, R.A.M.C., and Captain DOUGLAS, R.A.M.C., a total of four Victoria Crosses gained by their corps in the South African War. We are glad to observe also that Captain DUKA, of the Army Medical Corps, Queensland Defence Force, whose conduct at Elands river was lauded by all the defenders of that post, has been awarded a Distinguished Service Order.

We sincerely congratulate all the recipients upon their well-earned honours; but we cannot congratulate the authorities upon the *Gazette* as a whole because its fairness is so grievously marred by the omission of the name of the Director-General of the Army Medical Service.

THE GROCERS' RESEARCH SCHOLARSHIPS.—Applications for the Grocers' Livery Company's Medical Research Scholarships (value £250 each) should be made by letter to the Clerk of the Company, Grocers' Hall, Princes-street, E.C., during the present month.

Annotations.

"Ne quid nimis."

THE QUALITY OF TEA.

IT is being pretty freely stated that unwholesome tea is being imported into this country in large quantities and it is urged that steps should be taken to check the importation of inferior teas by closing the doors of the Custom House against their sale. The deterioration of the quality of tea is said to be owing to the introduction of machinery for tea-making, a process which produces a very inferior article compared with hand-made tea. Thus there is very little machine-made tea now which can be compared with the old finest quality China tea. The explanation of this lies, according to a tea-planter, in the inefficiency of machinery in its earlier stages of development to imitate the finesse of a skilful hand craftsman in carrying through a series of delicate operations. The difficulty arises, of course, from the fact that it is one thing to make a specimen article at a high price for the few and another to make it for the masses by the ton, and the grower is sure to be in favour of producing quantity rather than quality. It is said that millions of pounds of decomposing leaf are made into tea simply because many factories are insufficiently equipped. Tea undoubtedly requires delicate handling during the progressive stages of its manufacture. The methods of treatment, unless efficiently conducted, are necessarily hazardous to the quality of the final product. The leaf, of course, has to be plucked, then withered, rolled, and finally "fired" or dried. It is obvious that any one of these processes might involve injury to the quality of the tea, and the enormous scale on which tea is prepared for the market would have a tendency to introduce inefficient treatment at some stage or other. It is the same story as in so many things—the machine-made article can never compare with that made by hand. But any deliberate tampering with tea should be instantly stopped. It is said that modern processes frequently set up secondary fermentations, the true aroma of tea being thereby lost and replaced by the musty smell of mucic fermentation. We should have thought that these changes would have made the tea so nasty that no one would drink it. There can be no question, however, that we hear much more frequently than hitherto the expression, "I cannot drink tea," and whether or not this is connected with the enormously increased output of tea and the necessarily rapid means employed for its manufacture is an interesting and important question.

THE BUDGET.

IT is without doubt being brought forcibly home to the people of this country that war is an expensive method of settling disputes. Into the question of who is responsible, and therefore who should pay, for the present war, we shall not enter, but the fact is that money has to be found somehow, and those who have to find it naturally do not like the process. Income-tax presses heavily upon many of us; in fact, if we may believe the statements made by correspondents in the columns of the *Standard*, such a tyrannical tax has never existed since the day of ship money. On the other hand, a correspondent of the *Daily News* of April 24th sheds bitter tears over sugar. "Are Jingo and bully synonyms? The sugar tax does not affect the working man. ...... It means that the women will have to pay at least 1*s*. to 2*s*. more a week while the little ones will have to do without their sweeties, in many cases the only thing to brighten their little lives." This letter gives a wonderful picture of the working man's home. We believe that the new duty on sugar will add one halfpenny per pound to the retail price. According, therefore, to the *Daily News* correspondent the average working man and his family consume from 24 to 48 pounds of sugar, including treacle and jam, per week. No wonder that the out-patient departments of hospitals are crowded with dyspeptics. As to income-tax, it may be allowed for certain, we think, that incomes arising from inherited property should be taxed at a much higher rate than a man's earnings.

THE TRAFFIC IN OLD HORSES.

IN another column will be found a letter from Mr. John Colam, the secretary to the Royal Society for the Prevention of Cruelty to Animals, dealing with an annotation on the above subject in THE LANCET of April 13th, p. 1095. Mr. Colam's letter is somewhat elliptical, but we presume that he wishes to imply that the order of the Board of Agriculture which we quoted does not apply to horses while on the way to the boat, but only when they are at the wharf or on board. Otherwise why does not his society proceed under an order by which heavier penalties can be exacted than under the Cruelty to Animals Act? Is it because persons convicted of travelling lame or infirm horses through the streets, albeit such horses are on the way to a boat for shipment, cannot be punished under the order in question? It is always a perilous task to try to put a meaning to Acts of Parliament or to orders of Government departments. But to our minds the order of the Board of Agriculture concerning the exportation of horses certainly considers them while in the streets of the port of arrival. The order distinctly lays down the illegality of conveying in a vessel from any port in Great Britain "any horse which ...... cannot be so conveyed without cruelty during the intended passage *and on landing*" (the italics are ours). Surely these last three words must mean conveyance or passage from the ship to the slaughter-house or sausage factory. Surely, then, the order would also refer to the conveyance of horses from the market or other starting place to the ship at the port of departure.

EPILEPSY AND CRIME.

DR. JOHN BAKER, deputy superintendent of the Broadmoor Asylum for Criminal Lunatics, has published an interesting paper on Epilepsy and Crime in the April number of the *Journal of Mental Science*. Regarding epilepsy as a functional degenerative neurosis, characterised by motor, sensory, or psychical convulsions, the following types of epilepsy are recognised—viz., epilepsia major (*grand mal*) and epilepsia minor (*petit mal*), either of which may be associated with abnormal mental states occurring in close association with the fits or independently; and psychical epilepsy without motor convulsions. With regard to the co-existence of epilepsy with perfect sanity it is noted that whereas nearly half of all cases of epilepsy are sane, yet a tendency to mental enfeeblement is always threatened even in these cases. Epilepsy is common among the criminal classes. Thus Ottolenghi found that out of 265 criminals 80 were epileptic. Of these no less than 78 are described as cases of psychical epilepsy and they were variously denominated—vertiginous, unconscious, and automatic with or without violence. Dr. Baker thinks that pure psychical epilepsy, without any kind of motor convulsions, is so rare that its employment as a defence for crime must be regarded with great suspicion. Since the opening of Broadmoor Asylum in 1863 the number of patients admitted has been 2435—viz., 1860 males and 575 females. Of these 139 males and 26 females are described as epileptic. The crimes and offences committed were in order of frequency as follows: murder 68 instances, attempts to murder 41, larceny 28, arson seven, and burglary six. The remaining crimes included manslaughter, rape, forgery, and other offences. A marked disproportion exists between the epileptics of both sexes as regards the tendency to crime. The proportion of male epileptics who commit crime is much above the proportion of females. This may be due partly to the fact that the psychical activity of man is greater than that of woman, or, as Lombroso avers, to the tendency which the disease, when existent in women, has to assume the form of wantonness, which, however reprehensible in itself, is less dangerous and does not lead to sensational crimes requiring imprisonment. Moreover, as Tonnini remarks, epilepsy in women has a greater liability to cause imbecility and mental enfeeblement rather than the more active and dangerous form of insanity. Thus out of the small number of female epileptics present in Broadmoor Asylum in 1890 more than half display this tendency to mental enfeeblement without violence, not because of age and infirmity, but simply as a characteristic of the disease. The remainder retain their impulsive and dangerous propensities. Homicide is mostly committed during post epileptic automatism or post-epileptic furor, and there may be total or partial amnesia as regards the deed when normal consciousness is regained.

GARBAGE-MONGERS.

WALTER POWELL of Taff's Well, Caerphilly, is a butcher, and according to his own account is a young man in business, newly married, and has his character to make. Unfortunately, Mr. Powell's methods of character-making have brought him into contact with the law, for recently he was summoned at the Llandaff Police-court for exposing for sale meat unfit for human food; and also for selling horseflesh without giving proper notice to the public. A quantity of meat, both beef and horseflesh, the whole weighing 187 lb., was seized in the defendant's shop, and upon being condemned by a magistrate was destroyed. It was all unfit for food. Defendant's brother was seen to fetch the horseflesh from the knacker's and bring it to the shop, where the defendant took it and carried it into the shop. It must be said in defendant's favour that when the police and the medical officer arrived that he made no attempt to hinder them from inspecting his meat. The magistrates, we are glad to see, did not inflict a fine but sent defendant to prison for three months. For this period of time he will, at any rate, be fed with wholesome food despite his anxiety to poison his fellow creatures We do not know what the occupation of Mr. Brinley Powell, the brother, may be, but he certainly aided and abetted his brother in his iniquitous action, and we trust that the authorities will keep an eye upon him. We may add that defendant confessed that he gave 2*d*. per pound for the horseflesh and sold it for 5*d*. per pound, thus making a handsome profit.

THE DEPOSIT OF THE THERMAL SPRINGS AT BATH.

THE chemistry of the thermal springs of Bath was discussed at some length in the report of THE LANCET Analytical Commission of Oct 14th, 1899, p. 1068. In this report a series of analyses of the three historic springs was given and our Commissioners obtained some fresh results, showing amongst other things the presence of two constituents not hitherto recorded. We have since received specimens of a deposit found in the main pipe of the spring known as "the Hot Spring." As this pipe has not been opened for about 20 years the examination of this deposit should be of interest. The deposit presents the appearance of the ordinary incrustation obtained in boilers. Here and there the deposit was streaked with green which proved to be due to copper, an observation which would tend to confirm an analysis made by Sir Henry Roscoe of the Bath waters when he reported a trace of copper. The complete analysis of the deposit was as follows :—

Moisture	5·84	per cent.
Organic matter	1·30	,,
Silica	1·48	,,
Iron (oxide)	1·20	,,
Calcium sulphate	6·49	,,
Calcium carbonate	83·04	,,
Magnesium carbonate	0·65	,,
	100·00	,,

It will be seen that broadly the deposit consists chiefly of chalk with a little sulphate of lime. Spectroscopic analysis did not disclose any rare constituents, but of course any rare constituents in the water would most probably be soluble. As a matter of fact, in previous analyses of the water we found distinct evidences of the presence of lithia, strontia, and bromine.

A NEW CANCER HOSPITAL IN MOSCOW.

AN institution for the exclusive treatment of patients suffering from the various forms of cancer (either curable or incurable) is being built at Moscow at the expense, which is said to be an enormous one, of the municipality of that city. It is understood, however, that the main object which prompted the decision of the municipal authorities of Moscow of erecting a special hospital for cancer is to provide the necessary means for studying the nature of the disease from every possible point of view, and thus to encourage and to enable more thorough pathological and clinical research to be carried out in connexion with that malady. It is hoped that by carefully conducted scientific investigations the light of knowledge will be thrown upon a scourge which has of late years, and particularly in the northern regions of the Russian Empire, assumed a most formidable extent and character. The new institute, it is stated, will be under the entire management of a committee consisting of several members of the medical faculty with Dr. Lewschin, professor of surgery in the University of Moscow, as its Director; moreover, it is announced that special facilities will be offered to such students, desirous of joining the scientific circle of investigators there, who have already proved themselves good workers in that department of pathological research. In addition a special journal will be published by a committee selected for that purpose; it will bear the name of the said institute and will be entirely devoted to its scientific and social interests.

PROFUSE HÆMATEMESIS AND SYMPTOMS OF GASTRIC PERFORATION WITHOUT DISCOVERABLE LESION AT THE NECROPSY.

MR. MAYO ROBSON has recently called attention to the curious fact that after hæmatemesis, so severe as to be fatal, careful post-mortem examination may fail to reveal any lesion to account for the hæmorrhage.[1] The following case recorded in the *Intercolonial Medical Journal of Australasia* by Dr. H. G. Chapman is an example. A domestic servant, aged 27 years, was admitted to hospital on Nov. 24th, 1900, complaining of great weakness and vomiting. Two days before admission she had vomited a basinful of blood. She had been under treatment for gastric ulcer for 17 weeks. She was extremely anæmic and weak. She had taken nothing by the mouth except ice for two days. The pulse was 120. The abdomen was tender in the upper part and there were some rigidity and retraction. She was fed for two days on nutrient enemata. An attempt to give milk and soda-water produced vomiting and was abandoned. About one o'clock on Dec. 6th she was suddenly seized with pain which was followed by vomiting. At 3 P.M. there were slight distension and marked rigidity of the abdomen. Liver dulness was completely lost. The patient was collapsed and perspiring freely. Perforation was diagnosed and laparotomy was performed at 5 P.M. The stomach was brought entirely outside the abdomen but no abnormality could be found. A search for perforation of other viscera revealed nothing. The wound was closed and a large brandy and saline enema was given. The patient did not rally but vomited "coffee-ground" material for some hours. She was given strychnine and digitalin hypodermically and saline and brandy enemata every four hours. On the evening of the next day 1500 cubic centimetres of saline solution were infused into the median basilic vein. She never rallied and died early on Dec. 9th. Though the alimentary canal was carefully examined from the œsophagus to the sigmoid flexure no ulcer or abrasion could be found. In the stomach were dark brown fluid and a few clots. There was no sign of peritonitis. Slight degenerative changes in the shape of yellow patches in the aorta and on the aortic valves were found. It was thought that specific arteritis was present and that a small vessel had ruptured into the stomach causing the hæmorrhage. But the cause of the final attack which simulated gastric perforation remains quite unexplained.

ARSENIC IN STOCKINGS.

WE print an interesting communication this week in which it is shown that arsenic sometimes occurs in dyed stockings. Indeed, dermatitis has been traced to the wearing of stockings containing arsenic. The arsenic appeared to be present partly in a soluble and partly in an insoluble form. In an article in THE LANCET of Oct. 28th, 1899, p. 1186, we ourselves directed attention to the curious list of mineral substances that were found in dress materials. We failed, however, to find arsenic in any one specimen of the material submitted to examination, although we found present salts of zinc, aluminium, chromium, tin, magnesium, and iron. In one case, that of pink flannel, the material was loaded with Epsom salts. The materials examined were all more or less brilliantly coloured with aniline dyes. In recording the results of this inquiry we remarked that from time to time dermatitis had been referred to the use of highly dyed fabrics, and although dyes may not be injurious *per se*, yet certain poisonous agents, such as mordants, may be used in their preparation. Thus arsenic is largely used in colour making and dyeing and the poisonous metal has been found in small quantity in coloured dress fabrics. As we have said, we failed to detect arsenic in the materials, but in spite of the fact that all the aniline colours coming from Germany have been free from arsenic since the passing of a law in 1887 there would appear to be now, in the light of this recent inquiry, a recrudescence of the employment of arsenic in the dyes used, at any rate in stockings. This fact only shows what a sharp watch must be perpetually kept up in order to check an objectionable practice. There can be little doubt that in the cases cited the arsenic in the stockings was introduced through the dye. It appears to us that it should be the rule of the dyer to obtain a guarantee from the maker of the dye that it is free from arsenic altogether or at any rate as free as it is possible to be made by the best known process of elimination. It would seem that the employment of arsenic and its compounds, or of substances contaminated with arsenic, will inevitably have to be placed under special regulations, for apparently the presence of arsenic is unavoidable in a very great number of materials. The Royal

---

[1] THE LANCET, Feb. 9th, 1901, p. 376.

Commission on arsenic should include in their inquiry the question of the danger arising not only from arsenical food products but from arsenical clothing also, and should decide upon the limitations of the amounts of arsenic in any case.

THE ASSAULT ON A COMMISSIONER IN LUNACY.

ON Tuesday, April 16th, two of the Commissioners in Lunacy, Mr. G. H. Urmson (legal) and Dr. Sidney Coupland (medical), were paying the annual visit of inspection to the London County Asylum, the Heath, Bexley, when in Male Ward J. 2 a patient made a homicidal attempt on Mr. Urmson. Mr. Urmson, after visiting the patients and conversing with them, had re-entered the ward to ascertain if the numbers were correct when he received a violent blow upon the lower jaw, the weapon being the broken blade of a rusty table knife about two inches in length. Mr. Urmson had fortunately half turned round so that the blow did not fall on the neck as the patient had intended but upon the jaw. The wound, which was about one and a half inches long, bled freely, and was immediately treated by Dr. C H. Bond, the senior assistant medical officer, who was acting as deputy for the medical superintendent, Dr. T. E K Stansfield. The wound has rapidly healed without any complications. As regards the motive of the attack, it appears that the assailant had taken a dislike to one of the members of the Visiting Committee and had secreted the implement until occasion should serve for him to use it against that gentleman. But learning that the Commissioners were in the building he thought it an opportunity to use his weapon. He seems to have mistaken Mr. Urmson for one of the Prison Commissioners who had visited him when he was confined in Parkhurst Prison previously to his admission into the asylum, and when Mr. Urmson's attention was drawn away dealt him a blow which, but for a happy sudden movement on the latter's part, might have had fatal results. It should be added that all the patients are regularly searched, but in this instance the man had placed the weapon in hiding and had only withdrawn it shortly before he used it The assault on Mr. Urmson has many features in common with the fatal assault on Mr. Lutwidge, a legal Commissioner in Lunacy, which took place at Fisherton House Asylum nearly 30 years ago. Mr. Lutwidge was suddenly attacked by a criminal lunatic while making a visit of inspection at Fisherton House, the weapon, a nail which had been secreted by the murderer some time beforehand, being driven with one furious blow through the squamous portion of the temporal bone into the right hemisphere. Mr. Urmson seems to have narrowly escaped a similar dreadful fate, only the circumstance that he turned his head just as the blow was being struck saving the great vessels of the neck from injury that probably would have been fatal. We are glad to learn that Mr. Urmson has progressed so favourably and we congratulate him heartily on his providential escape.

ON CERTAIN NERVOUS CONDITIONS ASSOCIATED WITH ENTEROPTOSIS.

DR. JAMES ARNEILL in a paper published in the April number of the *American Journal of the Medical Sciences* refers to the frequency and importance of a group of nervous symptoms associated with enteroptosis and usually met with in anæmic and neurasthenic individuals of both sexes. The age of the patient was generally above 20 years, but after the climacteric period in women or the age of 60 years in men these cases were rare Gastroptosis usually coexisted with enteroptosis, and both were due to a relaxation and atony of the peritoneal attachments of the stomach, small intestines, and colon arising from feeble innervation. The mental symptoms consisted of depression and tendencies to melancholia, nervous irritability, and a proneness to hysterical manifestations. From a detailed study of 80 cases Dr. Arneill concluded with Meinert that in a large proportion chlorosis was also present, though he could not accept the latter condition as the cause An undue laxity of the tenth rib—the "costal stigma" of Stiller—characterised nearly all cases, and in many cases "nervous dyspepsia" was present. Many patients had a tendency to hypochondriasis and went from one physician to another. They suffered from general muscular atony even when appearing plump and well-nourished, were lacking in energy, and were easily tired. On examination of the abdomen while in the standing posture there was a sinking in of the epigastrium, while the abdomen was unduly prominent and big below the navel. Palpitation was common and in some a pulsating and tender aorta was observed. Inflation of the stomach with carbon dioxide gas—by administering tartaric acid and bicarbonate of soda—showed that the organ was displaced downwards Dr. Arneill states that in congenital cases of enteroptosis hyperacidity of the stomach was the rule. Blood examination of 23 cases showed that one was normal, nine were chlorotic, and 13 were anæmic but not chlorotic. Many of the female patients suffered from "floating" kidney or displacements of the uterus and in the former case operations had not infrequently been performed but benefit seldom resulted. Treatment consisted in massage of the abdominal muscles, properly devised mechanical support of the abdomen, lavage of the stomach and administration of hydrochloric acid in cases of subacidity, and the administration of tincture of nux vomica. Aggravated cases required prolonged rest and special treatment suitable to the degree of neurasthenia present Special conditions, such as intestinal obstruction and pelvic troubles in women, called for special treatment.

THE COUNTESS OF DUFFERIN'S FUND.

THE National Association for Supplying Female Medical Aid to the Women of India has been the means of relieving much suffering among the vast populations of our Indian possessions, and we are happy to see that its philanthropic work is being more and more appreciated by those whom it seeks to benefit. Its sixteenth annual report, dealing with the events of the year 1900, is issued by the Office of the Superintendent of Government Printing in Calcutta and forms with its 12 appendices a volume of 190 closely printed pages. The statistical part shows that during the year 1900 in India 1,667,329 women received medical treatment in 247 hospitals officered by women, the distribution of cases being as follows:—A. Patients treated in hospitals wholly maintained by the Association: in-patients, 7184; out-patients at the hospitals, 211,904, treated at home, 1635 B. Patients treated in hospitals aided by the Association: in-patients, 9450; out-patients at the hospitals, 258,300; treated at home, 2712. C. Patients treated in hospitals maintained from other sources—i e, independently of the two sources indicated under A and B: in patients, 26,028; out-patients at the hospitals, 1,136 804; treated at home, 13,312. The staff employed in the various hospitals for women throughout India includes 37 medical women of the first grade—i.e., persons qualified for registration in the United Kingdom. The names and qualifications of these ladies, together with the names of the hospitals where they are stationed are given in full, and the report is embellished with portraits of six of them. In addition to them there are also 80 assistant surgeons or practitioners of the second grade who have been trained in India and hold Indian qualifications, and 289 female hospital assistants and diplomates in midwifery filling appointments. The appendices contain much information as to the medical education of women in the United Kingdom and in India, together with particulars of the medals, scholarships, and prizes for which students are eligible. For the large number of Indian women who are debarred by religious and social prejudices from consulting male practitioners the action of the Association is of inestimable benefit.

THE SALARY OF THE MEDICAL OFFICER TO THE DAVENTRY WORKHOUSE.

MR. C. E. OLDACRES, the medical officer of the Daventry Workhouse, has been refused an increase of salary and has resigned his post under circumstances which should make other medical men pause before they apply for the vacancy. Mr. Oldacres has held office for 10 years at a salary of £30 per annum. On a previous occasion a rise in salary was refused to him because the work was said not to have become heavier since he accepted office. It is apparently not denied that the work is now harder, but the authorities will not give Mr. Oldacres the £50 per annum which is the least sum for which in justice to himself he can discharge the duties of the appointments.

VETERINARY WORK IN BENGAL.

IN the annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1899–1900, much information is given as to the prevalence of disease among domestic animals in and around Calcutta. Glanders appears to exist to an alarming extent; out of 188 draught ponies in the municipal Gowkhanas in Calcutta 102 were destroyed on this account. The stables in which the ponies were kept were described as being unsatisfactory, and Veterinary-Major F. Raymond, F.R.C.V.S., of the Civil Veterinary Department, had recommended that all the ponies should be tested with mallein, those that failed to pass the test being destroyed. Rinderpest also was fatal in an unusual degree. In one district alone it was reported to have carried off 27,000 head of cattle. The report gives details of the inoculation of cattle with bile on the Aligarh dairy farm, where rinderpest broke out on April 16th, 1899. Inoculation began on May 13th and the outbreak ceased on June 7th. The herd consisted of about 388 animals. 65 animals died before the inoculations, 15 died while the inoculations were progressing, six developed the disease a few days after they had been inoculated, and three contracted the disease about 10 months after the inoculation, during another outbreak. Altogether 291 animals, mostly cows, were inoculated; of these 70 buffaloes and 26 Zebu cows were in calf; but none of them aborted as a result of the treatment. Six developed rinderpest after inoculation (three died and three recovered). Five were possibly infected at the time of inoculation, but this did not apply to the sixth which was attacked 22 days after inoculation. The manager of the farm thought that the outbreak had been stopped by the bile treatment. Three of the cattle inoculated in May, 1899, died from rinderpest in March, 1900, from which it may be inferred that the buffalo bile treatment had been protective for 10 months.

A NEW PUBLIC HEALTH BILL.

A BILL dealing with the status of officers of health has been brought in by Sir Francis Powell and others and was ordered by the House of Commons to be printed on April 2nd. The text of the Bill is now before us and a memorandum appended to it states that the main objects of the Bill are to ensure that none but those properly qualified shall be appointed as officers of health and to give them the same amount of security in their tenure of office as prevails in Scotland, and as Poor-law medical officers possess in England and medical officers of health have in the metropolis. The Bill also deals with the question of superannuation allowances and proposes that the term "sanitary inspector" shall be universally used in place of "inspector of nuisances." The memorandum also points out that under existing laws urban and rural sanitary authorities may appoint officers of health on such conditions as to qualifications and tenure of office as they think fit. But highly technical duties are required of sanitary inspectors and one object of the Bill is to secure that they should be duly qualified. The term "officer of health," as used in the Bill, includes a medical officer of health, an inspector of nuisances, a sanitary inspector under the Public Health Acts of 1875 and 1891, or either of them, and a district or assistant sanitary inspector. The Bill shall come into operation from, and immediately after, Sept. 29th, 1901. The qualifications of an officer of health under the Bill are to be a certificate of the Local Government Board, or from some body approved by that Board, that he has shown himself by examination competent for office or that he has for three consecutive years before the commencement of the Act served as an officer of health. An officer of health may be suspended by a local authority at their discretion, and an officer of health may resign on giving one month's notice in writing. The whole Bill consists of 32 clauses. It is backed by, amongst others, Sir Walter Foster, Dr. Farquharson, and Sir Michael Foster.

EPISTAXIS IN PEOPLE BEYOND MIDDLE AGE.

A PAPER which we published in THE LANCET of April 20th, p. 1133, by Dr. George Coates, entitled "On the Causation and Treatment of Profuse Epistaxis in People beyond Middle Age," presents many points of interest. The effects of continued high arterial tension are frequently overlooked, or the resulting symptoms are attributed to other causes. One of the consequences of high tension is hæmorrhage, frequently from the lungs, but always from the relatively weakest point, and, as Dr. Coates expresses it, "it is probable that the venous sinuses in the noses of these sufferers from epistaxis have very thin walls." Dr. Coates considers that the sequence of events which lead up to the epistaxis is as follows: (*a*) long-continued high arterial pressure; (*b*) some sudden cardiac failure; (*c*) overfilling of the whole venous system, the weakened heart not being able sufficiently to empty the engorged veins against the high pressure in the arterial system due to contracted arterioles; and (*d*) leakage from an overfilled vein. Dr. Coates deduces these causes from five cases, giving a very brief account of each. We wish that he had given some more details, especially in regard to previous history. He mentions, however, that he had known and watched all the patients for several years both before and after the attack; therefore his remarks on the condition of the heart are of considerable value. Three out of the five cases "developed" valvular mischief coincidently with the attack of epistaxis. It is a well-recognised fact that prolonged exercise tends to lower arterial pressure, but during the first stages of muscular exertion the range of blood-pressure is high, especially in those persons unaccustomed to severe exercise. But in the cases mentioned by Dr. Coates there is no information as to whether there was a history of any physical strain immediately preceding the epistaxis and valvular failure. In heart-strain the valve that most usually suffers is the aortic and it is singular that in two out of the three cases in which there was valvular mischief, the mitral valve should have given way. The treatment adopted by Dr. Coates was perfectly rational. As a rule, in cases of epistaxis plugging the nares is at once resorted to, without sufficient attention being directed to the conditions causing the hæmorrhage. By giving nitro-glycerine the general blood-pressure was lowered, consequently the over-distended venous system was relieved and the epistaxis ceased, and Dr. Coates rightly remarks that "the immediate treatment must be directed to the capillaries and small arteries, as the real cause of the epistaxis lies there, not in the nose" Measures may subsequently be taken to improve the condition of the heart.

RETIREMENT OF DR. BROUARDEL.

PROFESSOR BROUARDEL, the Dean of the Paris Faculty of Medicine, has announced that at the end of his present term of office—namely, in February, 1902—he will not accept re-appointment This announcement has profoundly moved not only the medical profession but also the general public among whom Dr. Brouardel is well known and very popular. All sorts of reasons are given for his retirement, but his own reason for the step is simply that he is tired and considers that he has earned a right to rest

"THE ROYAL ORTHOPÆDIC HOSPITAL."

WITH reference to our editorial note to Mr. H. H. Marks's letter on the above subject published in our issue of last week, p. 1167, we think it right to inform our readers that we have received another letter from Mr Marks in which he supplies an answer to our question, but as he has requested, "in the interests of the hospital, that it should not be made public," we are of course precluded from expressing any opinion with regard to the information with which he has supplied us.

THE BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

IN our issue of March 16th, p. 805, we noted that those interested in the above institution had determined to secure a successor to Dr. H. Ward Irvine. We now see by an advertisement which the honorary secretary of the institution has sent us, and which we have not inserted, that the committee want two successors—a physician and a surgeon. A minimum salary is guaranteed and private practice is debarred. The Birmingham Consultative Institution is therefore now nothing more than a medical aid society. Its governing body consists of a committee of laymen who wish to keep two medical men to do medical work for them. We await the result of the advertisement in the lay press with interest.

EPIDERMOLYSIS BULLOSA HEREDITARIA.

IN the April number of the *Maryland Medical Journal* Dr. Henry L. Smith of Baltimore describes what he regards as the first recorded case of epidermolysis bullosa hereditaria occurring in the negro This disease has been observed many times in white races, the earliest reference given in Dr. Smith's list of authorities being to Dr. Tilbury Fox's "Notes on Unusual or Rare Forms of Skin Disease," published at intervals in the first volume of THE LANCET for 1879. Various names have been given to this condition; the one adopted here seems to have been first employed by Köbner, writing in the *Deutsche Medicinische Wochenschrift* in 1886 Dr. Smith's patient was a mulatto girl, aged seven years, who had since early infancy been subject to a breaking-out of water-blisters on her hands, feet, buttocks, and scalp. The eruption began as small, itching pimples, which were rapidly transformed into tense vesicles varying in size from that of a small pea to that of a pullet's egg They remained about one week before breaking, and after drying up left a brownish discolouration but no scar. These blisters were numerous in the warm weather of spring and summer, and they rarely appeared during the winter. The father, who gave the history, had since his earliest recollection been at times a sufferer from the disorder. His mother had been also similarly affected. His wife had never miscarried and was the mother of eight children, three of whom—two brothers and one sister of the patient—had at intervals since their birth had the eruption A microscopical examination of the blood and the contents of the vesicles was made by Dr. T. R. Brown of Baltimore, who found that there was both a general and a local eosinophilia.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

ARRANGEMENTS are being made for a conversazione at the Medical Graduates' College and Polyclinic, 22, Chenies-street, next Wednesday evening. The reception by the President, Sir William Broadbent, will take place at 8 P.M., and some brief lectures will commence at 8.30 P.M. Amongst those announced to lecture are Mr. James Cantlie and Mr. Hutchinson. The latter will take as his topics (1) the Retention of their Leaves through Winter by Deciduous Trees, and (2) the Suppression of One Tusk in Elephants. The clinical museum will be open, and there will be displays of surgical instruments and other objects of interest. We understand that all members of the profession will be welcomed, especially strangers in London. The arrangements are in the hands of Captain A. E. Hayward Pinch, F.R.C.S Eng , to whom, at the above address, all communications should be addressed.

DURING the summer session Dr. Patrick Manson will give a course of lectures on Tropical Diseases at the London (Royal Free Hospital) School of Medicine for Women. The lectures will be given on Tuesdays at 4 30 P.M., beginning on May 7th. The course will be open to all qualified practitioners and medical students, and, as far as possible, the lectures will be illustrated by cases. Further particulars can be obtained from the secretary, 8, Hunter street, W.C.

THE dinner of the Edinburgh University Club of London will take place at the Holborn Restaurant on Wednesday, May 1st, at 7 15 for 7 30 P M., under the chairmanship of Lord Lister, President of the club It is expected that the dinner will be largely attended. Members intending to be present or to bring guests must inform one of the honorary secretaries, Dr James Taylor, 49, Welbeck-street, W., or Dr. G. A. Sutherland, 73, Wimpole street, W.

THE Archbishop of Canterbury will take the chair at the annual meeting of the Church Missionary Society Medical Mission Auxiliary to be held in St James's Hall on Tuesday next, April 30th, at 3 P.M The other speakers will include Mr. A E. Clayton, L R C P , L R.C S Edin. (West Africa); Mr. A T. Kember, L R C P , F.R C S. Edin. (China); and Mr. J. O Summerhayes, M R C S., L.R C.P. Lond. (India).

UNDER the presidency of Sir T Andros de la Rue, Bart., chairman of the council, a festival dinner in aid of the Royal Hospital for Diseases of the Chest, City-road, E C., will be held at the Hôtel Métropole on Monday, May 6th. The object of the festival is to raise £10,000 to purchase a freehold site, to build and to furnish a nurses' home, and to carry on the work of the hospital.

HIS MAJESTY THE KING, who, as Prince of Wales, has been patron of the Royal Orthopædic Hospital since the death of the late Prince Consort, has graciously acceded to the appeal of the governors to continue his patronage.

THE KING has also signified his pleasure in acceding to the request of the council of the Royal Medical

Benevolent College that he should become the patron of the institution.

MR. A. WYNTER BLYTH has been nominated as President-Elect of the Incorporated Society of Medical Officers of Health for the year 1901-1902.

AMONG the recent cases of plague at Cape Town are four European patients. A nurse at the Plague Hospital has died.

THE King has graciously granted his patronage to the Royal Hospital, Richmond, Surrey

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 1098.)

IX.

OUR SUGGESTIONS FOR THE RE-ORGANISATION OF THE ARMY MEDICAL SERVICE.

HAVING dealt with the report and suggestions of the Royal Commission we now arrive at the most difficult point—the attempt on our own part to suggest measures of reconstruction and reform. Although it is undeniably true that time is eventually the devourer of all things there is a sense in which it is premature perhaps so to regard it; for whatever may be the remote effect of its operations, time from day to day and year to year manifests itself as a reconstructor and revitaliser of some things which are destined to survive the touch of its effacing fingers for a long period. By a process of selection some things perish, leaving others in the greater prominence. And this, we fancy, will prove to be the case with the army medical service.

One of the most fatal mistakes which can be made is implied in the general belief that all deficiencies can be supplied in time of war by having recourse to civil aid. During the present war a large number of civil surgeons have no doubt been employed with great benefit to all concerned and hospitals have been fitted out by private bounty—some of them with an elaboration of comfort which left little or nothing to be desired and on a scale with which no Government could hope to vie. Nothing can be further from our intention than to say a word in depreciation of the efforts that have been made in this direction and in other directions. There is, and always will be, plenty of room for doing very needful, indeed essentially necessary, work of this kind on the part of the nation and of the various Red Cross societies. Still something more than this is obviously necessary. Whilst war is war no responsible Government can be entirely dependent upon, or rest content with, the provisions of private effort. There must in any case be a thoroughly organised, well-trained, and well-manned army medical service. The Commissioners recommend in their report that immediate steps should be taken at the end of this war to increase the permanent strength of the Royal Army Medical Corps and to provide for its speedy enlargement in times of great wars. They also recommend that inducements should be offered to insure the continuous supply of sufficient men of good professional attainments and that means should be adopted for keeping them *au courant* with the results of medical progress so as to secure a high standard of professional efficiency. As regards the speedy enlargement of the medical corps in time of war our present system of medical reserve is quite inadequate for the purpose. Medical officers on the retired list, but liable to serve again, are not generally fit to do more than to take the place at home of those ordered abroad. Medical service in the army with its frequent and long foreign tours is an exhausting service and men age prematurely and suffer in health in many ways which unfit them for any further hard and exhausting work, so that other sources must be looked to. Seeing that for financial reasons it would be impossible to maintain a permanent medical establishment of sufficient strength to meet the requirements of any big war prosecuted on a modern scale, it seems essential that the establishment that we have should be of the best in training, experience, and efficiency and should be capable of being expanded whenever the occasion arrives. The numbers of the Royal Army Medical Corps must be increased, then, but that does not seem to us to be by any means all that is required. It is not the mere growth of the corps so much as its development that is needed. Our present army medical system is based on sound principles, but it is still in a state of immaturity. What should now be considered is the advisability of some comprehensive scheme, to include not only the regular medical service as an integral part of the army, but the medical services of the militia, volunteers, and colonial forces, supplemented by as much medical aid as is needful in time of war from the staffs of our civil hospitals and from the medical profession generally. Our statesmen proudly boast that the war in South Africa has converted the British Empire from a geographical expression into an accomplished fact. And if our colonies should be willing hereafter to take their share in supporting the Imperial burden they will naturally and rightly expect to have a voice in questions of Imperial policy. There are a good many people who think that in the future there will be required not so much a defensive home army as an Imperial army, and what seems to be wanted under the new and altered conditions of the British Empire is a scheme of organisation which will result in the practical formation of an Imperial Medical Service.

There is every reason to believe that the desire of the War Minister and the trend of public opinion are favourable to the making of such improvements and to the carrying out of such reforms as are necessary to place the medical service of the army in a position which will command the respect and approval both of the medical profession and of the public and will enable it to be prepared for the eventualities of war. Mr. Brodrick's public utterances have, however, been somewhat enigmatical as to his intentions. He declared on one occasion that he was prepared to adopt even drastic measures of reform if necessary, and on a subsequent occasion he intimated that he hoped to be able shortly to bring forward a new and satisfactory scheme for dealing with the army medical service. There is no disguising the fact (which was, indeed, admitted by a late Secretary of State for War) that the army has of late years ceased to have any attractions for the most talented alumni of our medical schools and colleges. We are not at all sorry for any delay that may take place in the introduction of a new scheme, because the matter is one that requires to be considered deliberately. Meanwhile there are some questions which urgently press for attention, such as the readjustment of the rates of pay of medical officers serving in India, the very large and disproportionate amount of foreign as compared with home service, and the way in which medical officers when serving at home are harassed by frequent moves and changes of station to the inconvenience and possible detriment of their patients and their own personal discomfort. We know, of course, that much of this is entirely attributable to the undermanning of the medical service and the exceptional demands caused by the war. Let the circumstances and explanation be what they may the present state of tension cannot be prolonged indefinitely. The campaign in South Africa has not only been a fight with physical geography throughout its whole course but a contest against new weapons and hitherto untried tactics. As regards the medical service, it has been conducted under circumstances of the most exceptionally difficult character and such as were altogether beyond the control of that service. The service must not be placed in such a position again.

Life is short and art is long and, indeed, very complex and diversified in the present day. In order to attain success, whether in our universities, in science, in literature or in art, there is no place for men like Bacon, who took all knowledge for his province; on the contrary, the tendency nowadays is for young men to begin to specialise early in their careers, each to take up his own special fragment of knowledge and to cultivate it to the utmost. This tendency, to the regret of many thoughtful and wise people, is a growing one in the medical profession as in other branches of scientific pursuit. Nor is this to be wondered at, for where so much depends upon knowledge of methods and detail, upon laborious painstaking, upon skill, and upon facility of manipulation, it is beyond the scope of anyone to cope equally well and at the same time with the art of modern surgery in all its branches and with medicine, hygiene, medical statistics, and hospital management. The officers of a public medical service such as that of the army have perforce to do this in a measure, but it is most unreasonable to expect that they can be experts in all subjects alike. What is, however, practically capable of being accomplished is that they should all have an opportunity of refreshing their professional knowledge and that anyone endowed with ability and aptitude in any direction likely to prove advantageous to the State should have all reasonable facilities for exercising these qualities. If such facilities were granted even to a limited member of men, the privilege being guarded against abuse in any way deemed requisite, we should have medical officers proceeding to the highest qualifications in medicine and surgery and these would constitute the pick of the service. The Director-General should, moreover, in the course of time have such a knowledge and record of the capacities, qualifications, and characters of his officers as to enable him at any moment—as on the outbreak of war, for example—to put his finger upon the right men to fill the right places. One of the main objects of the introduction of a general or consolidated medical system instead of the regimental one was to acquire such knowledge by putting medical officers in the exercise of their hospital and professional duties in competition with one another and in the presence of those who were qualified to form an opinion of their work instead of those who were not. But, like many other projects, it failed or proved futile. There are no means, or very few, of rewarding medical officers for professional distinction or scientific work in the service; and, speaking generally, promotion by selection has been apparently attended with so many difficulties that it has never been strictly adhered to. There should, in our opinion, be far more rewards held out for professional merit.

The German Empire is essentially a military Power. That *being so, looking to the geographical position of Germany* and the greater centralisation of political power in that country, we might expect that there would be a military organisation and pattern impressed upon, and running through the web and woof of, its governing and social fabric, and our expectations would be justified. In this country, where we have no compulsory military service and arrangements have to be made for periodical tours of foreign service on the part of our army, and where so much political power, freedom, and independence exist among the masses, things are different. National systems have grown out of national needs, but such systems have to be suitable to the character of the people and have, moreover, to be moulded and to be adapted to the existing environing conditions. It may be said that the German Government, owing to its one-portal system of government qualification to practice, has a lien and a claim on every medical man's services, and each of them has in time of peace the military rank and the post assigned to him which he would occupy in time of war. The best known university professors are accorded a military rank corresponding to the social and scientific positions which they occupy, and they act as consultants to the medical officers of the army in the field or at base hospitals in time of war and as their clinical instructors in time of peace There is, moreover, an elaborate system by which medical officers and others are not only attached to hospitals for duty and systematically put through special courses of instruction, but many of the senior medical officers are selected and entrusted with responsible hospital work of all kinds where their duties are not confined to military patients only but embrace civil patients. The forthcoming imperial autumn manœuvres to be held this year in the province of Prussia will show how keenly alive the German Government is to keep pace with military progress, and to bring any new methods and new inventions of warfare to the test of experimental trial. At the moment of writing these articles we learn that the medical department of the German army is to be reorganised; that candidates will be subjected to special examination in military surgery; that medical officers will make tours in future, under the guidance of the surgeon-general, similar to those made by the officers on the general staff; and that sanatoria are to be established for each army corps. In any case, without slavishly copying or following out all the details of the German system it should be possible to take the object and principles underlying that system as a framework for constructing a scheme of our own. Even without assigning beforehand military ranks and titles to all to whom it was proposed to apply in the civil walks of the profession for their aid and coöperation in time of war, there are a good many things that could be done which, it seems to us, it is highly desirable to set about doing. The more important European military Powers have in some respects outstripped this country in the race for medical efficiency in the field and in the importance which they attach to giving to their medical officers increased facilities for study and to having their hospital arrangements and equipment ready with both officers and men properly trained in their use. Not only should field hospitals be complete in every respect, but the whole service should be organised as a body of independent units capable of acting separately or combined. It goes without saying that medical officers should be encouraged in every way to avail themselves of every opportunity, both here and on the continent, of becoming practically acquainted with systems of army medical administration and with all the latest appliances and the results of modern researches. Merely theoretical and book knowledge will do little or no good and will be of little or no service to the State or to the individual. Actual experience and skill in the application of new methods and practices, these have a significance of their own compared with which other acquisitions of theoretical knowledge are of relatively insignificant value.

In outlining a scheme for the remodelling of the army medical service we recognise all the difficulties of the task and we are not vain enough to believe that anything that we can put forward will be so complete, self balanced, and practicable as to commend itself to all, and still less that there will be any finality about it. Let it be taken for what it is worth, and as put forward thoughtfully and in all good faith. The biggest and boldest policy is sometimes the best and the cheapest policy in the end, and in any case it may supply a standard which can be worked up to in the future.

The Status of the Director-General.

1. We propose that the Director-General as directing head of the whole medical service should occupy such a position, receive such a salary, and preside over, and be aided in his work by, such a headquarters' bureau as may be deemed worthy of the post which he holds and its responsibilities; and further, that the Director-General should have direct access to the War Minister when he deems it necessary in the public interest. The functions and responsibilities of the Director General are of an altogether exceptional as well as of an arduous character and are such as seem to us to require that he should have the right of access to the Secretary of State in order to submit personally his views and recommendations on grave or emergent matters, such as questions affecting the preparations for war and the sanitation and health of the army, instead of having them filtered through one of the heads of the departments of the War Office.

The Army Medical School in London

2 The Army Medical School should be in London instead of at Netley, and we think that for choice it should be called the "Imperial Medical Service Institute" or "Imperial Medical Service School." We believe that we fully appreciate all that can be said for and against this proposal, and we have come to the conclusion that the arguments in favour of removing the school from Netley to the metropolis greatly preponderate. It is no doubt a serious difficulty that there should be a Royal Victoria Hospital and an attached school already established at Netley and we can quite understand that this fact might in itself be deemed prohibitive of any change. But we do not think that it need be so. Netley as a medical school is inconveniently distant from London. The hospital, notwithstanding its fine and imposing appearance, is, as we think will be generally admitted, not up to the present sanitary standard. But the hospital might remain where it is, it could still be utilised as at present for our transported invalids, and the medical candidates could be temporarily stationed there if necessary during the height of the invaliding season from India and other foreign climates. All coming to this country—including, of course, all medical officers—find themselves in London, and it seems therefore only right and fitting that a medical school of such importance should not be located in the country but in the capital. When the Royal Victoria Hospital was originally built, in the lifetime of the Prince Consort and of her late Majesty Queen Victoria, the site was probably chosen owing to its proximity to Osborne and to the facility which it

offered to the Queen for showing the great interest which Her Majesty always felt in her sick and wounded soldiers. But the monarch will not necessarily be found at Osborne, while London is permanently the capital of the Empire, the place where all congregate. With the number of hospitals in the metropolis, and the extent and variety of injuries and diseases of all kinds to be seen there, London affords an amount of medical and surgical experience and practical information which are procurable probably nowhere else. Access is quickly obtained to most parts of London and almost every conceivable form of instruction is to be had as well as information regarding other places, such as universities and schools abroad. It is not simply going through a course at a special military school or hospital that the medical officer requires on returning from foreign service. He desires to have opportunities of attending post-graduate courses, of studying, and of observing the practice at various hospitals and schools both at home and abroad. If an Imperial Medical Service School were established in London the more cosmopolitan it were in character and the wider its portals were thrown open the better would it be. Not only should its course of instruction be open to all medical officers of the army and of the navy but also to all medical officers of the Indian Medical Service, militia, volunteers, and colonial corps who happened to be in this country and who cared to avail themselves of it. It would be regarded as a distinction and privilege to be a professor in such an institution, and the very publicity of all the proceedings connected with it would very materially tend to attract men of eminence and to keep its appointments free from jobbery and abuse.

GREATER FACILITIES FOR INSTRUCTION OF MEDICAL OFFICERS.

3. Medical officers should be encouraged in all professional studies and in making themselves acquainted with the methods of army medical administration, hygiene, and equipment of other countries. Leave should be granted to them for this purpose and for taking out special courses of instruction both in this country and on the continent, certificates being exacted to insure that the time was actually spent in pursuit of the intended object.

ABOLITION OF ENTRANCE EXAMINATION.

4. We recommend the abolition of the present entrance competitive examination of candidates for the Army Medical School but the retention of the examination on all the subjects which they have been taught there before leaving the establishment and being commissioned as officers of the Royal Army Medical Corps. In the first place, the entrance examination has ceased to be competitive. Moreover, the competitors have all recently become qualified and have therefore had to undergo repeated examinations during their course of study, and they should have already shown their quality by the hospital posts which they have held and by the degrees and diplomas which they have taken. Any further re-examination for the army is naturally distasteful to the large majority of them, and it seems to be superfluous and unnecessary to subject a man to professional tests similar to, or identical with, those to which he has already just been subjected in order to obtain his qualifications to practise. It is not at that time but at a subsequent stage of his career as a medical officer that the desirability or necessity of an examination test comes in; therefore let there be substituted a competitive examination for medical officers in the place of that now in force for candidates on entrance. It cannot be necessary to place or to grade the candidates in some order of priority from the beginning.

PROPOSED EXAMINATIONS.

5. The examination of the medical officer in substitution of the entrance competitive examination of the medical candidate might be taken somewhere within the first ten years of the officer's service, the time to be chosen by the medical officer and regulated by the convenience of the service. Such examination should be of two kinds, one a compulsory and pass examination, the other a voluntary and special or honours examination. (*a*) In the pass examination a certain standard of proficiency should be exacted in order to show that the officer has kept himself reasonably acquainted with the progress of surgery, medicine, army hygiene, and army medical organisation and administration (all to be as practical and pertinent to army service and hospital requirements in peace and war as possible). (*b*) The honours examination should be voluntary in any subject or subjects that the candidates may select, such as military surgery, medicine, epidemiology, hygiene (including bacteriology), &c. A separate list should be kept of the honours men and their names should be marked with an asterisk or some distinguishing letters as is now done with officers who have passed the staff college (*p.s.c.*).

INSTRUCTIVE MILITARY MANŒUVRES.

6. In all military manœuvres in which a composite force of regulars, militia, volunteers, and colonial corps take part the mimic warfare should be as like real war as practicable. The hospital and medical part should be on one uniform and organised plan with some sort of unification of all the medical services and their officers, so that they may rehearse in times of peace what would be actually required of them in war, every man knowing his place and being in it. Everything should be carried out as on active service in the field, but on a reduced and miniature scale, of course, and field, stationary, and general hospitals should be represented. Experimental trials should be made of a system by which general hospitals could be split up and divided into smaller units to meet the exigencies of war, as in the case of long and impracticable lines of communication, change of base, or the temporary provision of more than one base. The surprises and other unexpected occurrences of war might be counterfeited so as to test the promptitude and judgment of medical officers under all sorts of conditions; and one or more of them might be selected in turn to design, to organise, and to arrange for the medical requirements of a force at such manœuvres, forwarding their proposed schemes to the principal medical officer under whom they are serving.

DELEGATION OF CERTAIN EXISTING DUTIES OF THE ROYAL ARMY MEDICAL CORPS.

7. To the question asked by the Royal Commissioners in their report, "Whether it is advisable and practicable to some, and if so to what, extent, that the Royal Army Medical Corps should have exclusive possession of and control over all necessaries for the sick and wounded (other than ordinary food and clothing, not being hospital clothing), so as to avoid the necessity of requisitioning upon the Army Service Corps or the Ordnance authorities," our reply would be that it is both advisable and practicable, but not in the way indicated by the Commissioners. It seems to us that medical officers in time of war are, as a rule, overwhelmed with work and responsibility and that they are expected to carry out—that is, to execute—duties which should be discharged by others who should act under the direction of, and subordinate to, the medical service. In order to guard against any misapprehension we may say that medical officers must, under the general officer in supreme command, have independent control over everything coming within their legitimate functions and sphere of duty, but that is no reason why they should have to discharge all the duties appertaining thereto. *Qui facit per alium facit per se.* There are a number of outside duties of a purely military or *quasi*-military character, such as drill, charge of animal transport, the drawing of rations, the purchase of food and stores, &c., of which they might usefully be relieved by, let us say, the Army Service Corps, if men of that corps were specially told off to carry out their orders. The *Intendance* of the old French army system became intolerable because it exercised its power in hospitals over the heads of the medical officers instead of under them. The medical officers of the French army have for many years now been completely emancipated from the control of the *Intendance*, and the French medical service has, perhaps, a more perfect autonomy than is the case in any other European army. But we are not without a precedent in modern military history for the kind of arrangement which we have in view. There is nothing of such importance in connexion with field medical administration as transport; it is, as it were, as the linch-pin of a cart or the pivot on which the success of the hospital system in war turns. The Americans notably found this to be the case in their great war, and in 1864 a most important Act was brought before Congress by the War Department and passed into law. The ambulance transport was completely separated from the other transport services of the army and was placed under the direction of the head of the medical department who had not only the direction of the

vehicles for the carriage of the sick and wounded but also that of the officers and men employed, subject only to the general authority of the officer commanding the forces in chief. The medical director or chief medical officer of an army corps had simply to issue his orders to those in charge of the ambulance, and the quartermaster-general's department was relieved of all authority and responsibility in the matter. We should like to see a practical trial given to a system by which the Royal Army Medical Corps, while still possessing all necessary power and responsibility, could be relieved of duties of a more purely military kind, such as the charge of transport animals and the purchase of stores. It should be sufficient for them to issue the orders, they should be spared the responsibility of execution. There is a possible danger connected with this power to purchase on the part of the medical service which should not be altogether lost sight of—namely, that the supply departments might relax their efforts to meet a medical officer's requirements in consequence of the knowledge that the latter could purchase in the local markets, and an unfair strain and responsibility might thus be entailed on the medical service.

CORPS UNIT MEDICAL OFFICERS.

8. Every corps unit should have a medical officer *attached* to it who should remain with it for a definite time (say five years) in order to familiarise him with the habits, customs, and regulations of military life, to avoid the inconvenience and discomfort to patients of frequent changes of medical officers doing duty with the officers, men, women, and children of a corps, and to furnish some one reliable medical man to whom the officer commanding and all in the corps could apply. The medical officer doing this duty might, wherever practicable, take his part in professional work at the station hospital and in the occasional garrison duty common to all. A regiment has a medical officer with it in war and it is for the mutual benefit of both that it should have one in peace also. In the armies of France, Germany, Austria, Italy, and Russia the system in force, as a general rule, combines the advantages both of the general and regimental systems. Every battalion has its medical officer. In Germany and Austria the regimental medical officer does departmental duty in the general hospital, while in France, Italy, and Russia he attends the sick in the regimental hospitals or infirmaries which are established for the treatment of minor cases.

BARRACK DISPENSARIES.

9. We think that a barrack dispensary system could be advantageously introduced into the British army and that small station or depôt hospitals might, to some extent, be done away with, as they are frequently a waste of money and energy. Arrangements might be made for utilising civil hospitals, wherever practicable, for the purpose. A notable feature in the French army is the utilisation of civil hospitals for military medical service. The soldier patients might be under the care of medical officers, as was the case, we believe, not long ago in Edinburgh. The men of the Royal Army Medical Corps should be trained on both sides so as to have the advantage of a medical (ward) standard as well as a military (disciplinary) standard. For infectious diseases in the army existing civil hospitals for infectious diseases should as far as possible be utilised on the score of economy.

DUTIES OF MEN OF THE ROYAL ARMY MEDICAL CORPS.

10. The men of the Royal Army Medical Corps should be thoroughly trained in their duties as hospital orderlies and cooks. War is exceptional, and when it occurs the inefficiency from sickness is invariably much in excess of that from wounds. It follows that men who have to act as hospital orderlies should be trained in those duties which they are most commonly required to fulfil, in peace and war alike. Their hospital (ward) dress should be of a suitable character. Military drills should be reduced as far as possible. The duties of the hospital orderlies are of too miscellaneous a character They learn their company and stretcher drill and from their military associations and surroundings are, perhaps, too apt to exalt the importance of military in comparison with medical matters. It is not easy to serve two masters, the tendency being to hold to the one and to despise the other, the other in this case being the medical side of their duties. The men of the corps are, nevertheless, as a rule, excellent and zealous in their work. It will be seen that we concur with the Commissioners in their suggestion that the officers of the corps should, so far as is consistent with a due maintenance of discipline, relax the strict military rule generally adopted in hospitals so as to give an additional feeling of ease to the patients and to enable them better to appreciate the comforts of a hospital. We think, moreover, that the medical officer in charge should make a practice of periodically going round with his medical staff and of identifying himself with their professional work as much as possible by inquiring into the nature, causes, and treatment of the cases. If he has any remarks to make or suggestions to offer it is needless to add that he should pay due regard to professional ethics.

FEMALE NURSES.

11. Without skilled female nurses nursing cannot be properly carried out and it will probably be necessary under ordinary and existing circumstances to increase the existing establishment. It will certainly be so in case of war on any large scale.

SUPPLEMENTARY HOSPITAL PERSONNEL.

12. With a view to being ready to supplement the regular army medical service to any required extent in case of war we consider that the following registers or lists should be prepared and kept in the medical branch of the War Office: (1) a nominal list of those members of the junior staffs (medical and surgical) of all the more important hospitals in the United Kingdom and of the colonies who would be willing in case of need to proceed to the seat of war and to give their professional services (an annual retaining fee would be money well laid out for this purpose); (2) a similar list of trained female nurses and of nursing institutions, as well as of Red Cross societies and other philanthropic bodies with the estimated amount of available aid which they could respectively furnish in time of war. The civil element should be very freely utilised in war at general and stationary hospitals and, of course, in private hospitals sent out as supplementary aid to the medical provision afforded by Government. In cases of great pressure or emergency the civil element might largely take over the hospital duties at the base and at the rear, and so free the military medical element for the work in front where it would be most urgently needed.

FIELD HOSPITAL UNITS.

13. There should be some field hospitals organised and working as complete and independent hospital units, on the lines of a field battery of Royal Artillery at our camps and garrisons, ready to take the field with their existing establishments. Were it so and were these field hospitals practised on every available occasion, it should be easy, on the mobilisation of troops for active service, to attach transport from the general transport of the army, together with a certain proportion of a bearer company, and to allow the whole to embark as a field hospital unit ready to take the field at once. In this way officers and men who had worked together in times of peace would maintain the same relations in war, harmony would be secured, and the competition between one field hospital and another would excite wholesome emulation.

POINTS CONCERNING ABOVE.

14. The following points should be considered with a view to their final settlement:—The attachment of bearer companies to field hospitals for employment in connexion with them when no fighting was taking place and their services were not elsewhere required; the size and equipment of field hospitals (which must obviously always be kept as light and mobile as possible and have only a limited supply of stretchers instead of bedsteads); the size and equipment of stationary and general hospitals and the divisibility of the latter into smaller sections—say of 100 beds (of a lighter and narrower kind of bedstead than those now in use); the nature and amount of hospital transport; and arrangements for the possible supply of a large force of Indian dhoolie-bearers in case of need.

SANITARY CORPS.

15. Assuming, as we assuredly may, that special sanitary officers will be appointed and will form part of any future military expedition, the question will also have to be discussed whether any sanitary body or corps for executive sanitary work should be organised, and, if so, whether it should be affiliated to the Quartermaster-General's department or that of the medical service or should have a special and separate existence under the orders of the chief sanitary officer. It would be scarcely practicable to employ untrained

civil labourers on first effecting a landing on an enemy's soil. What might possibly meet the occasion would be a large and well-organised body for executive conservancy work in connexion with the Quartermaster-General's department.

RESERVE OF STORES.

16. The reserve medical stores kept on hand must obviously be calculated on the number of army corps or force maintained on the home establishment as efficient, ready, and designed for the express purpose of offensive warfare. It is equally obvious that the most portable and compressed forms of medicine and drugs must largely enter into the list of preparations intended for field service, that the number and variety of these must be restricted to those of well-known and established reputation, and that medical officers and others must learn that bodies of troops operating in the field cannot be accompanied on service by a section of wholesale dispensing chemists and their drugs, and that what may be termed a "great run" on any particular drug when others would suffice equally well has to be carefully avoided. It is a question whether a certain amount of shipping transport could not be placed entirely at the disposal of the Director-General, so that medical stores, accompanied by a supercargo provided with lists of everything on board, could be sent out in the transports and hospital ships for field service use.

LIGHTENING OF CLERICAL WORK IN THE FIELD.

17. The conduct of the business transactions connected with field service seems to us to be susceptible of improvement in the way of more directness of aim and simplification, and this might be effected by taking a leaf out of the method adopted in civil life, as at the various Coöperative Stores, for example With the view of instructing medical officers, the officers of the supply departments, and all concerned with the field medical arrangements, as well as with the object of decreasing the amount of clerical labour and of facilitating the conduct of business as far as practicable, a portable handbook or *précis* of these arrangements should be published by authority and used as a general guide. This should be issued on the order for mobilisation and be considered as binding on all concerned during a campaign. It should not only succinctly set forth the different scales of hospital equipment provided, but the different sources of supply to which requisitions and applications have to be addressed, together with condensed notes of a practical character. This was, we believe, done with practical advantage on the occasion of some of the Afghan campaigns. A *précis* of field medical arrangements was published under the sanction, and with the authority, of the military department of the Government of India. Every medical officer should be supplied with a copy of such a portable handbook as we are referring to, with a carbon book for making short communications and requisitions on departments, a small almanac-diary, and a medical certificate form-book, these should be all that are personally necessary for his use. Other documents and forms of returns could be kept at the field, stationary, and general hospitals. With the agency of the carbon book a duplicate of any communication or requisition addressed to individuals would be preserved, and these, with the entries in the diary, would remain as a permanent record, so far as they went, of the medical transactions in the field and could be handed in as so many vouchers at the end of a campaign. All that related to more elaborately prepared documents and returns connected with the official medical transactions and history of the war should be relegated to the hospitals furnished with a more or less permanent staff of medical officers and provided with the requisite clerical aid.

TREATMENT OF CONVALESCENTS.

18. Among the subjects which might be usefully taken up for consideration at the present time, when a large number of invalids have already returned, or are returning, from the war, is the question of the greater utilisation of military hospitals and barracks situated in favourable districts for convalescing soldiers requiring change of air and for such as need special hospital accommodation and treatment—the open-air treatment of pulmonary tuberculosis, for example. The sites occupied by some of the Government hospitals and buildings are so salubrious and good that it seems to be a pity to restrict the advantages to the sick, suffering for the most part from trifling ailments, drawn from the troops quartered in the neighbourhood. We have not yet heard of any movement in the army in the direction of the open-air treatment so successfully adopted in certain forms of pulmonary disease.

HOME MILITARY HOSPITALS.

19. The opportunity should be taken in the interest of the sick soldier to inquire into the subject of the management of home military hospitals, concerning which an article by Mr. W. Pugin Thornton of Canterbury was recently published in these columns.[1] As Mr. Thornton's paper professes to be largely based upon a statement of facts and sets forth the results of a personal experience acquired in a military hospital it seems to us to be well deserving of attention at the present time.

MEDICAL PRACTITIONERS AND UNQUALIFIED (PHARMACEUTICAL) ASSISTANTS.

A JOINT meeting of the Glasgow Southern Medical Society, the Glasgow and West of Scotland Branch of the British Medical Association, and the Glasgow Eastern Medical Society was held in Glasgow on April 17th, Dr. WILLIAM WATSON, President of the Glasgow Southern Medical Society, being in the chair.

It was unanimously resolved that the following memorial should be forwarded to the General Medical Council:—

> That the memorialists are medical practitioners in Glasgow and the West of Scotland and have a right at common law, in virtue of their degrees granted by the Scottish universities and of their diplomas granted by the three qualifying corporations of Scotland, to sell drugs and poisons, including the scheduled poisons under the Pharmacy Acts. That the liberty of selling drugs and poisons (except scheduled poisons) belongs to every British subject and the memorialists are under no disability in this respect merely because they are members of the medical profession. That the rights and privileges of the memorialists as medical practitioners to sell drugs and poisons, including the scheduled poisons, are expressly reserved by Parliament (32 & 33 Vict, cap. 117, section 1). That the memorialists have learned with surprise and alarm of a conviction of a registered medical practitioner on a charge in the following terms: "That he, being a registered medical practitioner, habitually employed as assistants for the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants, and thereby causes such persons to commit breaches of the Pharmacy Acts." The conviction is said to have been that the registered medical practitioner in question was guilty of "infamous conduct in a professional respect." The memorialists are bound to assume that conduct of a grave and reprehensible character was proved to the satisfaction of the General Medical Council before such a conviction could take place, but of the facts proved and the arguments used they have no knowledge. That a general impression has gone abroad that the only evidence against the registered medical practitioner in question was evidence in support of the charge as quoted, and that on this charge he was convicted of infamous conduct in a professional respect. That this view of the matter is publicly stated and commented on in trade journals, such as the *Pharmaceutical Journal* of Dec 8th, 1900, and the *Chemist and Druggist* of the same date, and no secret is made of the meaning of such a judgment—viz., altogether to deprive medical practitioners of the right to sell drugs and poisons. In the view of the memorialists this is an illegal and unwarrantable interference with the memorialists' rights, and they do not believe that the General Medical Council intended to lay down any such general doctrine or to impose any such disability. That a difference of opinion formerly existed as to the true interpretation of section 15 of the Pharmacy Act, 1868, some holding that the person who commits the offence under that section is the person who keeps open shop, to whom the poisons belong, and on whose behalf the sale is effected; others holding that the only offender under that section is the actual salesman. The latter view has received judicial sanction both in England and in Scotland, with the result that the salesman and not the owner of the shop is the person liable. That if the judgment of the General Medical Council in the case of the registered medical practitioner above referred to is to be regarded as a general statement of their views as to the responsibility of medical practitioners, it amounts to a reversal of the decisions of the law courts when interpreting section 15 of the Pharmacy Act, 1868. It makes the owner of the shop liable for offences under that Act, whereas the law has decided that the salesman and not the owner is the person liable. That under section 15 of the Pharmacy Act, 1868, a certain statutory penalty is imposed upon persons infringing—viz., a fine of £5; but the decision of the General Medical Council not only imposes a penalty upon persons not struck at by that section of the Act, but also imposes an entirely new penalty—viz., deprivation. Where Parliament has prescribed the penalty to be attached to any Act it is incompetent for the General Medical Council, or any other body except Parliament, to alter or increase the penalty. To subject registered medical practitioners to the risk of being struck off the Register because a salesman of theirs sells drugs or poisons is unauthorised by any Act of Parliament and is an unconstitutional assumption of statutory authority on the part of the General Medical Council. That the memorialists are not concerned to defend any medical practitioner who authorises his assistants to sell scheduled poisons. They recognise that, as the law stands, the utmost care should be taken to prevent such sales by anyone not duly authorised. But even in such an

---

[1] THE LANCET, March 30th, 1901, p. 958.

[illegible] view with alarm the attempt now being made [illegible] er [illegible] — [illegible] at [illegible] so- [illegible] a- [illegible] ve [illegible] he [illegible] are [illegible] assistants must not entitle [illegible] s of sell act [illegible] st to dispens [illegible] iders the co [illegible] the which [illegible] salesman himself, there is no restriction upon the employment of [illegible] or not. The memorialists cannot [illegible] n the part of a pharmaceutical [illegible] n a professional respect" on the [illegible] in some quarters the decision of [illegible] interpreted to mean that where [illegible] victed under the Pharmaceutical [illegible] he should, in addition to the [illegible] the Act of 1868, be subjected [illegible] dismissal at the hands of his employer, and that a failure on the part of an employer so to dismiss an offending assistant amounts to "infamous conduct in a professional respect." This view of th [illegible] has been already urged— [illegible] to the penalty imposed b [illegible] further objection that [illegible] no law requires, and what in many cases may be a very harsh act, is to be treated as infamous conduct Speaking generally, no omission of that kind can be properly so characterised Infamous conduct must consist of some overt act, not any omission But, apart from this, it can never be infamous to omit to do what no law requires to be done.

The memorialists, therefore, respectfully submit that this matter should be reconsidered and that, whatever be the special circumstances justifying the decision in the case of the registered medical practitioner above referred to, no general doctrine should be laid down to the effect that the employment by a registered medical practitioner of an unqualified person to sell drugs and poisons is "infamous conduct in a professional respect."

It was also agreed that the following gentlemen should be appointed a deputation to support the memorial before the General Medical Council—viz., Dr. John Lindsay Steven, Dr. Russell, Dr. G E. Robertson, Dr David Young, Dr. William Watson, Dr John Stewart, Dr. J. H. Nicoll, and Dr. John Y. Orr.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7385 births and 4159 deaths were registered during the week ending April 20th. The annual rate of mortality in these towns, which had been 19 2 per 1000 in each of the two preceding weeks, declined to 18 4 per 1000 last week In London the death-rate was 17 5 per 1000, while it averaged 19 0 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 10 8 in Burnley, 11 2 in Halifax, 11·9 in West Ham, and 12 3 in Cardiff; the highest rates were 22 7 in Manchester, 22 9 in Liverpool, 23 7 in Nottingham, and 25 4 in Wolverhampton. The 4159 deaths in these towns included 346 which were referred to the principal zymotic diseases, against 380 and 397 in the two preceding weeks; of these, 117 resulted from measles, 108 from whooping cough, 39 from diphtheria, 33 from diarrhoeal diseases, 27 from "fever" (principally enteric), 20 from scarlet fever, and two from small-pox No death from any of these diseases was registered last week in Croydon, Plymouth, Huddersfield, or Halifax; in the other towns they caused the lowest death rates in Norwich, Birkenhead, Oldham, and Newcastle, and the highest rates in Hull, Sunderland, and Gateshead The greatest proportional mortality from measles occurred in Portsmouth, Liverpool, Bolton, Blackburn, Leeds, and Sunderland; from scarlet fever in Blackburn, and from whooping-cough in Bristol, Hull, and Sunderland The mortality from "fever" and from diarrhoeal diseases showed no marked excess in any of the large towns The 39 deaths from diphtheria included 11 in London, four in Bristol, four in Manchester, three in Leeds, and three in Sheffield Two fatal cases of small pox were recorded in Hull, but not one in any other of the 33 large towns; and no small-pox patients remained under treatment in any of the Metropolitan Asylums hospitals on Saturday, April 20th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1526, against 1568, 1572 and 1601 on the three preceding Saturdays; 150 new cases were admitted during the week, against 167, 180, and 205 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 360 and 345 in the two preceding weeks, rose again last week to 374, but were slightly below the corrected average. The causes of 39, or 0 9 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Bradford, Leeds, and 16 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 24 1 and 23 2 per 1000 in the two preceding weeks, further declined to 23 0 per 1000 during the week ending April 20th, but showed an excess of 4 6 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 18 5 in Perth and 20 5 in Aberdeen to 26 7 in Greenock and 28 3 in Dundee. The 722 deaths in these towns included 56 from whooping-cough, 23 from diarrhoea, 21 from measles, 10 from small-pox, four from "fever" two from scarlet fever, and one from diphtheria In all, 117 deaths resulted from these principal zymotic diseases last week, against 102 and 95 in the two preceding weeks. These 117 deaths were equal to an annual rate of 3 7 per 1000, which was 2 2 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of whooping-cough, which had been 57 and 51 in the two preceding weeks, rose again last week to 56, of which 37 occurred in Glasgow, 14 in Edinburgh, two in Dundee, and two in Paisley The deaths from diarrhoea, which had been eight and 13 in the two preceding weeks, further increased to 23 last week, and included 12 in Glasgow, five in Edinburgh, and four in Dundee The fatal cases of measles, which had been 16 and 17 in the two preceding weeks, further rose last week to 21, of which eight were registered in Edinburgh, five in Dundee, four in Leith, and two in Glasgow. The deaths from small-pox, which had been 10, five, and six in the three preceding weeks, rose again last week to 10, and were all recorded in Glasgow, where two of the four deaths from "fever" and the two fatal cases of scarlet fever were also registered The deaths referred to diseases of the respiratory organs in these towns, which had increased from 126 to 155 in the four preceding weeks, declined again to 130 last week, and were slightly below the number in the corresponding period of last year. The causes of 34, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·9 and 35 6 per 1000 in the two preceding weeks, declined again to 35 4 during the week ending April 20th. During the past four weeks the death rate in the city has averaged 34 2 per 1000, the rates during the same period being 18 0 in London and 23 1 in Edinburgh. The 235 deaths of persons belonging to Dublin registered during the week under notice were within one of the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against 12 and 15 in the two preceding weeks; of these, nine resulted from whooping cough, four from diarrhoea, three from "fever," and two from scarlet fever. These 18 deaths were equal to an annual rate of 2 7 per 1000, the zymotic death-rate during the same period being 1·5 in London and 4 7 in Edinburgh. The fatal cases of whooping-cough, which had been five and eight in the two preceding weeks, further increased last week to nine The deaths from diarrhoea, which had been one and three in the two preceding weeks, further rose to four last week. The fatal cases of "fever," which had been four and two in the two preceding weeks, rose again to three last week. The mortality from scarlet fever corresponded with that in the preceding week. The 235 deaths in Dublin last week included 34 of children under one year of age and 65 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Twelve inquest cases and six deaths from violence were registered; and 98, or more than two-fifths, of the deaths occurred in public institutions The causes of 11, or nearly 5 per cent, of the deaths in the city last week were not certified.

THE SERVICES.

SOUTH AFRICAN WAR HONOURS.

THE King has given orders for the following promotions and appointments in recognition of the services of the undermentioned officers during the operations in South Africa. These rewards are for services in South Africa up to Nov. 29th, 1900, the day on which Field-Marshal Lord Roberts handed over the command. Owing to the multitude of recommendations forwarded to the Commander-in Chief it has not yet been possible fully to examine those for regimental service or those relating to the Militia Yeomanry, Volunteers, and certain other services.

ROYAL NAVY.

To be a Companion of the Distinguished Service Order:—

Staff Surgeon Ernest Courtney Lomas, R.N.

Staff Surgeon Lomas entered the service in 1891 as Surgeon and was promoted last year to Staff Surgeon for services in South Africa

THE ARMY.

To be Ordinary Members of the Military Division of the Third Class, or Companions of the Most Honourable Order of the Bath:—

Colonel William Flack Stevenson, R.A.M.C, Professor of Surgery at the Army Medical School, Netley; principal medical officer on the line of communication in South Africa.

Colonel (local Surgeon-General) James Francis Supple, R.A M.C.

Colonel Supple served in the Ashanti war of 1873-74 and was present at the attack and defence of the hospital at Foomanah (medal). He also served in the Afghan war of 1878-80 (medal) and with the Sixth Brigade (mentioned in despatches, medal and clasp).

Lieutenant-Colonel (local Colonel) William Donovan, R.A.M.C., principal medical officer, Cavalry Division.

Colonel Donovan served in the Afghan war in 1879-80 with the Cabul field force and afterwards with the Koorum force and took part with the Zarmusht expedition under Brigadier-General Tytler, in medical charge of the 85th King's Light Infantry, including the assault on Lawa (medal) He also served in the Boer war of 1881 with the Natal field force as a volunteer. He served with the Chitral relief force under Sir Robert Low in 1895 (mentioned in despatches, medal with clasp).

Lieutenant-Colonel (local Colonel) Oswald Gillespie Wood, R.A.M.C.

Colonel Wood served in the Egyptian war of 1882 and was present at the battle of Tel-el-Kebir (medal with clasp and Khedive's star).

Lieutenant-Colonel (local Colonel) Alfred Keogh, R.A.M.C.

Colonel Keogh entered the service in 1880 and reached the rank of Lieutenant-Colonel in 1900.

Colonel W. D. C. Williams, New South Wales Army Medical Corps.

To be an Ordinary Member of the Second Class, or Knight Commander of the Order:—

Sir William MacCormac, Bart., K.C.V.O., consulting surgeon to the forces.

To be Ordinary Members of the Third Class, or Companions of the Order, the following consulting surgeons to the forces:—

Sir Thomas Naghten Fitzgerald, Kt., Sir William Thomson, Kt., Mr. Alfred Downing Fripp, M V.O., Mr. George Henry Makins, Mr. Frederick Treves, M.V.O., Mr. William Watson Cheyne, Mr. George Lenthal Cheatle, Dr. Kendal Franks, and Dr. John Chiene.

To be Ordinary Members of the Second Class, or Knights Commanders of the Most Distinguished Order of St. Michael and St. George:—

Surgeon-General William Deane Wilson, A.M.S., Principal Medical Officer in South Africa.

Surgeon-General Wilson served in the Afghan war of 1878-80, and in the Soudan expedition under Sir Gerald Graham in 1884 as principal medical officer of the Infantry Brigade, and was present in the engagements at El Teb and Temai (mentioned in despatches, promoted Surgeon Major, with relative rank of Lieutenant-Colonel, medal with two clasps and Khedive's star).

Colonel Thomas Joseph Gallwey, C.B., R.A.M.C., principal medical officer of the Infantry Division in South Africa.

Colonel Gallwey served in the Afghan war of 1879 and was present at the attack and capture of Ali Musjid (medal with clasp). He served in the Egyptian war of 1882, and was present at the battle of Tel-el-Kebir (medal with clasp and Khedive's star); with the Nile expedition of 1884-85 when he had charge of the Debbeh Field Hospital and took part in the operations of the Desert column on its return to Korti (mentioned in despatches, promoted Surgeon-Major, clasp); and also with the Dongola expeditionary force, under Sir H. Kitchener, in 1896 as principal medical officer to the force, including the engagement at Firket and the operations at Hafir (mentioned in despatches, C B, British medal and Khedive's medal with two clasps). In 1897-98 he was principal medical officer with the Egyptian army and was present at the battles of the Atbara (mentioned in despatches) and Khartoum (mentioned in despatches, promoted to Colonel, two clasps to Khedive's medal). He was nominated to the third class of the Medjidieh for services under the Egyptian Government.

To be Ordinary Members of the Third Class, or Companions of the Order:—

Colonel Edmond Townsend, C B., R A.M.C., principal medical officer, 1st Infantry Division in South Africa.

Colonel Townsend was present at Belmont and Enslin. He served in the Abyssinian campaign from December, 1867, to June, 1868, and was present at the action of Arogee (medal). Served throughout the operations in the Malay Peninsula in 1875-76, including the actions of Jan. 4th, 14th, and 20th, and Feb 4th; severely wounded (medal with clasp). Served in the Zulu war of 1879 and present in the engagement at Ulundi (mentioned in despatches). Served in the operations against Sekukuni in 1879 and was present at the storming of the stronghold (medal with clasp) Served in the Egyptian war of 1882 and was present at the battle of Tel el Kebir (medal with clasp and Khedive's star) He also served with the Burmese expedition of 1885-86 (medal with clasp) and with the Ashanti expedition under Sir Francis Scott in 1895-96 (mentioned in despatches, star). In the campaign on the north-west frontier of India under Sir William Lockhart in 1897-98 he served with the Mohmund field force (mentioned in despatches) and was afterwards principal medical officer of the 1st Division of the Tirah expeditionary force (mentioned in despatches, C.B., and medal with two clasps).

Surgeon-Lieutenant-Colonel Henry Frank Hensman, retired May, late 1st Life Guards.

Surgeon-Lieutenant Colonel Hensman served in the Umbeyla campaign on the north west frontier of India in 1863 with the Durbund field force.

Lieutenant Colonel (now local Colonel) Arthur Thomas Sloggett, R.A.M.C.

Lieutenant-Colonel A. T. Sloggett served with the Dongola expeditionary force under Sir H. H. Kitchener in 1896, including the engagement at Firket and the operations at Hafir (mentioned in despatches, promoted to be Surgeon Lieutenant-Colonel, 4th Class of Osmanieh, and Khedive's medal with two clasps). He served also in the Soudan campaign of 1898 as senior medical officer of the 1st Brigade British Division, and was present at the battle of Khartoum (dangerously wounded, mentioned in despatches, promoted to the higher grade of his rank, 3rd Class of the Medjidieh, clasp).

Lieutenant-Colonel (local Colonel) John Francis Williamson, R.A.M.C.

Lieutenant-Colonel J. F. Williamson served in the Afghan war of 1878-79, and was present in the engagement at Charasiah on Oct 6th, 1879, and in the operations round Cabul in December, 1879, including the investment of Sherpore; accompanied Sir Frederick Roberts in the march to Candahar, and was present at the battle of Candahar (mentioned in despatches, medal with three clasps, and bronze decoration). Served in the Egyptian war of 1882, and was present at the battle of Tel-el-Kebir (medal with clasp, and Khedive's star). Served with the Burmese expedition in 1887-88 (medal with clasp). He also served in the campaign on the north west frontier of India under Sir William Lockhart in 1897-98 with the Mohmund Field Force (mentioned in despatches), and afterwards with the Tirah expeditionary force in the Peshawar column and the 5th Brigade (medal with two clasps).

Lieutenant-Colonel (local Colonel) Percy Herbert Johnston, R.A.M.C.

Lieutenant-Colonel Johnston served in the Afghan war of 1879-80, and took part with the Zarmusht expedition, including the assault of Lawz (medal).

Major (now Lieutenant-Colonel) Walter George Augustus Bedford, R.A M.C., secretary to the Principal Medical Officer in South Africa.

Lieutenant-Colonel Bedford entered the service in 1881 and became Surgeon-Major in 1893.

Major George Washington Brazier-Creagh, R A.M.C.

Major Brazier-Creagh entered the service in 1881 and became Surgeon-Major in 1893.

Major Frederick Samuel Heuston, R.A.M C.

Major Heuston served with the Hazara expedition in 1888 in medical charge of the 2nd Battalion Northumberland Fusiliers (medal and clasp).

Surgeon-Major (now local Lieutenant-Colonel) Charles R. Kilkelly, Grenadier Guards.

Lieutenant-Colonel Kilkelly entered the service in 1885 and became Surgeon-Major in 1898.

Major William Rice Edwards, I.M.S.

Major Edwards entered the service in 1886 and was made Surgeon-Major in 1898

Major Henry Alfred Cummins, R.A.M.C.

Major Cummins served with the Sikkim expedition in 1888 (medal with clasp).

Surgeon-Lieutenant-Colonel E B. Hartley, V.C., C.M S.C.

Surgeon-Lieutenant-Colonel Hartley served in South Africa as principal medical officer in 1877-1881 (medal with clasp). He received the *Victoria Cross for rescuing under fire the wounded at* Morosi's Mountain on June 5th, 1879

Dr. A. A Scot Skirving (Yeomanry Hospital).
Mr. J. P. Bush (Princess Christian's Hospital).
Dr. D. Wallace (Edinburgh Hospital).
Mr. H. E. Clark (Scottish National Hospital).
Mr. A. A. Bowlby (Portland Hospital).
Dr. H. H. Tooth (Portland Hospital).
Dr. J. W. Washbourn (Yeomanry Hospital).

To be Companions of the Distinguished Service Order:—

Major (now Lieutenant-Colonel) Richard William Ford, R A M.C.

Major R. W. Ford served in the Egyptian war of 1882 (medal and Khedive's star).

Major (now Lieutenant-Colonel) Thomas Joseph O'Donnell, R.A M.C.

Major O'Donnell served in the Egyptian war of 1882 (medal and *Khedive's star) and served with the* Bechuanaland expedition in 1884-85 and in the operations in Zululand in 1888. He served with the Kimberley relief force and was present at the action at Magersfontein (mentioned *in despatches)*

Major Robert James Leech Fayle, R.A.M C.

Major Fayle entered the army in 1882 and was promoted to Surgeon-Major in 1894

Major William Watson *Pike*, R.A.M.C.

Major Pike entered the service in 1882 and reached the rank of Major in 1894

Captain Ernest Chester Anderson, R.A.M.C.

Captain Anderson entered the service in 1892 and became *Surgeon-Captain* in 1895.

Captain John Hay Campbell, R.A.M.C.

Captain Campbell entered the army in 1896 and was promoted to Captain in 1898.

Captain Percy John Probyn, R A.M.C.

Captain Probyn *entered* the army as Surgeon-Lieutenant in 1896 and was promoted to Captain in 1899.

Captain Arthur Winsmore Hooper, R.A M.C.

Captain Hooper entered the army in 1696 as Surgeon-Lieutenant and reached the rank of Captain in 1899.

Lieutenant John Joseph Whitworth Prescott, R.A.M.C.

Lieutenant Prescott was with the Ladysmith *relief force* and was present at the battle *of Colenso and in* the operations on the Tugela including the engagement of Vaal Krantz. Was present at the engagements at Monte Cristo and Pieter's Hill and the *relief of Ladysmith.*

Lieutenant Henry Edward Manning Douglas, V.C., R A.M C.

*Lieutenant Douglas was present at the engagement at Magersfontein in which he was severely wounded and won the Victoria Cross.

Major T. H. Fiaschi, New South Wales Army Medical Corps.

Captain A. T. Duka, Army Medical Corps, Queensland Defence Force.

Captain Duka distinguished *himself* at Elands River.

Surgeon-Lieutenant (temporary Captain) C. B. Keenan, Lord Strathcona's Corps

Surgeon-Captain R. O Perkins, Brabant's Horse.

Surgeon-Major F. A. Holmden, British South Africa Police.

Captain J. J. Brownlee, Cape Medical Bearer Corps.

Surgeon-Major W F. F. Davies, Imperial Light Horse.

Captain G. E. Heberden, medical officer, Kimberley Light Horse.

Surgeon-Major J A. J. Smith, Kimberley Regiment.

Major J. Hyslop, principal medical officer, Natal Volunteers.

The following are noted for promotion:—

ROYAL ARMY MEDICAL CORPS.

To be Colonels:—

Lieutenant-Colonel (local *Colonel*) W. B. Allin, principal medical officer of the Infantry Division in South Africa.

Colonel Allin served in the Afghan war *of 1878-80* (medal), with the *Nile* expedition in 1884-85, and had charge of the *field* hospital at Gakdul Wells (mentioned in despatches, promoted Surgeon-Major, medal with clasp and Khedive's star) *He also* served in the Isogai expedition of 1892.

Lieutenant-Colonel (local Colonel) W. L. Gubbins' Assistant Director of the Army Medical Service.

Colonel Gubbins served in the Afghan war of 1878-80 and took part with the Bazar Valley *expedition under Lieutenant-General* Maude in medical charge of the 5th Fusiliers and subsequently of the headquarters *staff*; also divisional sanitary officer and secretary to the principal medical officer. *He* was present with the expedition against the Mohmunds and *into the Hissarek Valley* (medal) *He also served* with the expedition to Burmah in 1886 (medal with clasp).

To be Lieutenant-Colonel under Article 362 of the Royal Warrant:—

Lieutenant-Colonel (local Colonel) A. Keogh.

To be Lieutenant-Colonels:—

Major W. Babtie, V C., C.M.G.

* Major Babtie served in the occupation of Crete 1897-98 as senior medical officer (C M G). *He served in South Africa with the Ladysmith* relief force and was present at the battle of Colenso, where he earned his V.C.

Major D. Bruce.

Major Bruce entered the service as surgeon in 1883 and was promoted *to surgeon-major in 1895.*

Major L. E. Anderson.

Major Anderson served with the Nile Expedition of 1884-85 and in the subsequent operations in the Eastern Soudan in 1885 (medal with two clasps and Khedive's star).

Major H. G. Hathaway.

Major Hathaway served with the Burmese expedition in 1885-89, and accompanied the Ruby Mine column to Mogoke; was present at the [illegible] Capta [illegible] nder [illegible] relief [illegible] itral [illegible] Malak [illegible] the [illegible] orth- [illegible] the [illegible] ilion [illegible] and [illegible] wounded in the South African [illegible]

To be Majors:—

Captain T. B. Beach.

Captain Beach entered the army as Surgeon-Captain in 1891.

Captain C. W. R. Healey.

Captain Healey entered the service in 1891.

To be Captains:—

Lieutenant W. H. S. Nickerson, V.C.

*Lieutenant Nickerson entered the Army in 1893. He gained the Victoria Cross in the present campaign.

Lieutenant E T. Inkson, V.C.

*Lieutenant Inkson entered the army in 1899. He also won the Victoria Cross in the present campaign.

Corporal A. O. Ralfe, Corporal W. L. Glasgow, and Private F. A. Farrell are also noted for promotion.

Sergeant-Major F. Crookes to be granted a bar to the Distinguished Conduct Medal already conferred upon him.

* The records of the brave and gallant actions for which these officers earned the Victoria Cross will be found in the pages *of* THE LANCET as follows:—Major Babtie, V.C, April 28th, 1900, p 1220; Lieutenant Inkson, V.C, Jan. 19th, 1901, p 200; Lieutenant Nickerson, V.C., Feb 16th, 1901, p 507, and Lieutenant Douglas, V.C, April 6th, 1901, p. 1038.

MENTIONED IN DESPATCHES.

ERRATUM.—Dr. H. H. Tooth's name was by error omitted from the list of names mentioned in Lord Roberts's despatch published in the *London Gazette*, page 2599. *After* "the Portland Hospital, under Mr. A. Bowlby, F.R.C.S.," the words "and Dr. H. H. Tooth" should be added.

MEDICAL NOTES IN NORTHERN WATERS BY A FRENCH NAVAL SURGEON.

Dr. Aurégan of the French warship *Ibis* gives a deplorable account in the *Archives de Médecine Navale* for February of the insanitary conditions under which his compatriots have to live who, to the number of close on 5000 persons, are engaged in the North Sea fishery. Throughout the winter months these unfortunate men fish for mackerel in the Channel and off the coast of Ireland, but early in May they steer for the north of Scotland in search of herrings and, following the *shoals* as far even as the Shetland Islands, gradually sail down the North Sea until about the month of October they arrive at the *embouchure* of the Thames. In nearly every one of the 300 vessels that are engaged in the trade there is only berthing accommodation for about one-half of the crews at a time, while owing to the lack of bedding the men, as a rule, turn in "all standing," *no matter whether* their clothing be wet or dry, and for the most part retaining their heavy boots. Under these circumstances the smells pervading the dark, damp, unventilated cabins are naturally sickening, and to make matters worse in this respect the occupants are said never to wash themselves during the whole of the time they remain at sea. In the second part of his report Dr. Aurégan describes *some of* the hospitals which he visited while cruising in the *Ibis*. Except in England, where similar defects are not apparent, he is of opinion that, generally speaking, the medical wards of these establishments are too large and also that in several other important respects the medical sections fail to fulfil the desiderata of modern nosocomial hygiene. Under existing conditions classification and isolation are nearly always most difficult of attainment. Dr. Aurégan's account of the British hospitals which he inspected is brief but interesting. "At Aberdeen," he says, "the Royal Infirmary, a fine hospital of 450 beds, although of recent construction, occupies but a relatively small space. It consists of three-storeyed buildings, it is true, but these are divided up into wards for at most 20 patients. What strikes the visitor on entrance is the scrupulous cleanliness which reigns everywhere. One feels that the rules of hygiene are observed with the strictest rigour, a trait which is common to all the establishments of this kind which we have visited in Scotland as well as in England." Speaking of Edinburgh, with its "superb school of medicine," laboratories, and numerous hospitals, Dr. Aurégan, with reference to the Royal Infirmary, says: "This hospital with its annexes occupies a superficies of about 12 acres. Of recent construction and built entirely of granite it comprises 15 pavilions, each containing two wards, one above the other, for 20 beds. These pavilions are united by covered passages and those destined for surgical cases are in communication with magnificent operation-halls wherein the latest improvements of surgical science have been collected" In conclusion our friendly critic expresses himself equally favourably with regard to "the other towns of lesser importance, such as Grimsby and Lowestoft." In each port he found a handsome hospital where the sick from the *Ibis* and her "annexes" were always treated with the utmost kindness "These establishments, although smaller and less luxurious than the foregoing, are nevertheless very elegant (*coquets*) and in them the rules of hygiene are always most religiously observed."

PARKES MEMORIAL PRIZE.

The Parkes memorial prize, consisting of 75 guineas and a bronze medal, is awarded every third year to the writer of the best essay on a subject connected with hygiene. The competition is open to the medical officers of the navy, army, and Indian services of executive rank on full pay, with the exception of the assistant professors of the Army Medical School during their term of office. The subject for the last competition was "Venereal Diseases in the British and Indian Armies, their Prevalence and Prevention." Surgeon-General McD. Cuffe, C B, A M.S., Colonel K. McLeod and Major R H. Firth, R.A.M C., acted as assessors and awarded the prize to the essay bearing the motto, "Quis quid peccat in eo punitur." The writer of the successful essay was Captain Howell, R.A.M.C.

Correspondence.

"Audi alteram partem."

SMALL-POX IN NOTTINGHAM AND ELSEWHERE.

To the Editors of THE LANCET.

SIRS,—Small-pox has recently been introduced into the Mormon headquarters in this city, apparently by letters or other fomites, from Salt Lake City.. The first of our cases *appears to have had a very mild attack* and slight rash about Feb. 1st; the second, also a very slight one, had a rash commencing about Feb 21st. The third and fourth were somewhat more severe than the preceding, but still very slight, and their rashes dated from about March 24th. The fifth, another extremely mild case, began to develop a rash on April 14th, at which date I first became aware of these facts and at which also the entire household were removed to our isolation hospital. The above patients' ages ranged from 22 to 33 years. Four of them are unvaccinated, and one was vaccinated in infancy. The only regular member of the household to escape infection altogether was a vaccinated male, aged 24, who was re-vaccinated in 1895. I regret to say that the outbreak has been the means of communicating small-pox to at least six other places between Liverpool and Leicester, though in single cases only, I believe, in each instance up to the present. The special cause of this general dissemination was a small Mormon conference held in Nottingham on March 24th, at which date the rashes of the third and fourth local cases were developing. I am, Sirs, yours faithfully,

PHILIP BOOBBYER.

Health Department, Guildhall, Nottingham,
April 24th, 1901.

THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES.

To the Editors of THE LANCET.

SIRS,—As it was at my invitation that the representatives of the medical profession did me the honour on several occasions to meet the committee of the Friendly Societies' Conference at this office I ask your permission to offer a few observations on the present position of the question between them.

When Dr. Bruce, one of the Direct Representatives of the profession, suggested the formation of a joint Board of Conciliation the suggestion was felt to be a very happy one and it would be much to be regretted that it should fall through. I am therefore glad to observe that the Friendly Societies' Conference still expresses its anxiety to secure the appointment of a Conciliation Board for the settlement of disputes between friendly societies and their medical officers and has reappointed its committee to continue the negotiations. I was also glad to observe in Dr. Elliston's letter to the secretary of that conference the proposal that the Conciliation Board "shall be entirely unfettered in its deliberations and shall be allowed to try to find a remedy for every grievance of both sides" Unfortunately, however, as I venture to think, the letter proceeds to lay down what is called the "wage-limit" as a necessary preliminary to entering upon these deliberations and has been met by a declaration that it cannot be agreed to under any circumstances. Unless this attitude can be somewhat modified on both sides the Conciliation Board is not likely to be formed.

The real question is the proper remuneration of the medical man and the wage-limit is only a part of that question, and not, I think, so important a part as both sides seem to consider it. It has been quite pertinently asked, "Do the friendly societies ask for medical relief as a charity? or do they wish to sweat the medical profession? or are they willing to pay a fair price for the services rendered to them by it?" I know them well enough to answer the question without hesitation. They desire to pay a fair price for the services rendered to them. They are neither beggars nor sweaters. How is the fair price to be ascertained? The medical man is to say, taking the society as a whole, for what sum paid by every member, whether sick or well, he is willing to attend those who are sick. He fixes that price, not at the rate at which he attends upon the very poor, nor at the rate at which he attends upon the comparatively rich, but at the reasonable rate which will, on the whole, pay him for his services. If this remuneration were not collected for him by the friendly society he might, in some cases, fail to get it at all, for the obvious reason that a man may be able to pay a small yearly sum, but not able to pay a large doctor's bill. Now, how does the circumstance that after a time one or more of the members earns more than £120 a year, which is the proposed wage-limit, affect this contract? It can only injure the medical man if that particular member happens to fall ill and if the difference between the remuneration that member would have to pay as a private patient and that upon which the medical man estimates his claim to remuneration from the friendly society is greater than the amount the medical man gains by receiving remuneration from the friendly society in cases where he would have got none at all. In other words, the contract between the medical man and the society is based on an average, and if one patient is above the average there are others who are below it. If the loss to the medical man is greater than the gain, all he has to do is to revise his terms, not necessarily to exclude from the average any particular cases It is at that point that the operation of the Conciliation Board would be beneficial.

The constitution of a friendly society is essentially democratic. All join for the same benefit and pay according to their ages the same contribution. They do not consider anybody too good for them and do not care to be asked to exclude a member merely because he is rich. While they know there is much in the kindly services of the medical man that no money can purchase they are willing to pay such fair professional remuneration as on the average is found to be sufficient to retain those services. I venture, therefore, as an independent onlooker, to suggest to Skill and to Thrift, the two parties to this dispute, equally admirable and worthy of respect, whether the one need insist on absolute exclusion of a member by the wage-limit test, and whether the other need insist on the absolute exclusion of the wage limit test from consideration Conceding these points, I think they might again approach each other and, I trust, with good result

I am, Sirs, your faithfully,
E W. BRABROOK.

Registry of Friendly Societies' Central Office,
Abingdon-street, S W., April 22nd, 1901

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr Archdall Reid and I, like the *theologians*, not only come to different general conclusions from our common text-book, but we do not even agree as to its facts Rowntree and Sherwell state *explicitly that* "the total *per capita* consumption of absolute alcohol (in spirits, wine, *beer, &c*) *in Norway*" *in 1833* was "estimated" at *8 5 litres*, in 1843 at 5 5; in the quinquenniad 1851–55 the "actual" consumption was 3 9, in *1861–65* it was 2 7, in 1871–75 it was 3 6, in 1881–85 it was 2 4, in 1891–95 it was 2 6, and in 1894–98 (the latest returns) it was 2 4 How "drunkenness has greatly increased *in Norway of late years*" *on* a greatly diminished quantity of alcohol passes my comprehension. *The arrests for drunkenness form* a most fallacious basis of conclusion. I know a Scotch county in which *there* are *no* arrests for drunkenness, but I wish I could state that there is *no alcoholic excess there.* In a country whose authorities are keen to put down drunkenness, as *is* the case in *Norway now*, a few habitual inebriates each arrested *every* week will soon run up the arrests to *5 8 per 1000 inhabitants* in any of its cities I surely think that Dr. Reid will not deny that this evidence as adduced in Rowntree and Sherwell does as a whole fairly prove that recent *legislation in* Norway *has* diminished drunkenness and that in consequence the morals and the health *of the people there have improved*

I have just re read Dr. Archdall Reid's chapters on alcohol *in* "*The Present Evolution* in Man" with increased interest and undiminished admiration of *his sternly* logical mind But I am far from satisfied that he fully proves his case and that no other hypothesis than his will explain the facts I, and many others better qualified to judge *than* I am, absolutely dispute *his* cardinal theory "that the craving for alcohol, like sexual love, is an *instinct* not an acquired trait" We think his analogy is unscientific and his conclusi*ons based on it* fallacious, but we admired his ingenuity of mind, even when his theory led him *to the logical abysses* of "alcoholic retrogression," and to the proposition that "racial abstinence from *alcohol must have* for ultimate result only excessive racial indulgence in the poison" *Dr Reid's desire* to benefit *the race* is no doubt as great as that of any other thoughtful man. His whole *practical remedies* for the direful effects of excessive alcohol on mankind are thus summed up: "We *must either permit* alcoholic selection to run its level course or we must assist it by artificial *selection* and *so prevent much* of the misery by weeding out the obviously unfit—either by forbidding marriage to drunken *individuals*, or in the married by preventing the procreation of children by separating the *parents or* such other means as *science* may devise" He fully admits the bad effects *of* alcohol in excess *on the present* generation of men in health and morals. But because he is so *down on* the "diminution" *of the* "alcoholic supply," on "total abstinence, local veto, the Gothenburg *system*, &c.," as *measures that* "will—must—result in the aggravations of the craving for that *state* of mind which *indulgence* in alcohol induces," I and many *more* consider his alcoholic *theory* dangerous We also *think* his proposed remedies impracticable and *insufficient*. I cannot see *why a scientific* logician like Dr Reid should resent the logical outcome of his theory, *which* is certainly this: "*Alcohol* craving is a universal instinct; its only cure is alcoholic evolution; *therefore* let *us permit* alcoholic selection to run its cruel course"

Dr. Laing Gordon in his letter exhibits more zeal than discretion in defence of his master and more assurance than courtesy in his methods of controversy.

I am, Sirs, yours faithfully,
T S. CLOUSTON.

Edinburgh, April 22nd, 1901

To the Editors of THE LANCET.

SIRS,—I have done Dr Archdall Reid *the justice of reading* most of, if not all, his letters and papers on this alcohol and heredity question, but I am afraid I have not yet grasped his meaning. At *one time Dr.* Reid appears to me to deify alcohol and at another time he seems to recognise that there is a drink evil. Again, *his writings leave the impression* that he feels that alcohol has not had fair play, because if it had had fair play it would regenerate the human race by weeding *out* the weaklings and leave behind only those proof against its evil influences. The next time, *Dr. Reid varies his assertions by stating* that for 1000 years the old methods have been tried and found wanting. This practically means that King Alcohol has had absolute sway *for the space of* 1000 years, a sufficiently long one, one would have thought, for effecting the weeding-out and *regenerating* processes. In one communication Dr Reid tells us the peoples *whose experience* of alcohol is the longest and most intimate are those who are the least susceptible to its evil influence This runs counter to the history of the human *race*. All *peoples have known alcohol in some* shape or form from their remotest antiquity. Even such peoples as *the ancient Aztecs* and Peruvians, who had the beverages cocoa and teas of various kinds, had also alcoholic beverages. On the point relating to resistance, the *Germans were great drinkers so far* back as the days of Tacitus. Tacitus tells us that they drank strong beer and *often passed* an entire day and night in drinking, yet this long acquaintance with alcohol has not rendered them immune to its subtle influence, for only within the last few months the Socialists of Germany have become *so* alarmed at the ravages of alcohol that they petitioned the Legislature to take the *question* up Switzerland, like Germany, has had a fair experience of alcohol in one shape or another, and recently the Socialists of the various cantons have also presented petitions *fortified* by hard *facts telling of* the havoc of alcohol among the workers of their land. France has *long* had *her wines* and her people have not become immune to alcohol Surely Dr. Reid cannot be ignorant of the growing drink evil in fair France nor of the repeated pathetic *appeals to the Legislature* presented by the learned Academy of Medicine of Paris *crying for reform* because *of the evil* which alcohol is working among the people of France Spain, too, the land of *wines, shows* an alarming increase of drinking among her people. Now, according to Dr. Reid's theory, these *peoples* should all be immune to alcohol

Dr Reid's persistence is admirable but worthy of a better cause His may be described as the philosophy of pessimism *of the Schopenhauer* type with the humour left out No old Calvinistic divine more determinedly *preached the salvation* of the few and the damnation of the many than does Dr. Reid. But *the Calvinistic divine believed* in the awfulness of sin, whereas Dr Reid teaches the benignity of evil as seen *in the ravages of alcohol* Now suppose he were to apply the same process of reasoning to the small pox evil *which* he so trenchantly employs with regard to alcohol he would use the language of Epictetus and *the Stoics and say to the* citizens of Glasgow: "The outbreak of small pox in your midst is nothing. *It is salutary and it will* weed out the weaklings; then why do you try to stop its progress? Rather rejoice in *the visitation*" What would the citizens of Glasgow think of such advice? I am pretty sure the medical officer at least would imagine that Dr Reid had never heard of Francis Bacon and the experimental philosophy and that he had never heard of sanitation and vaccination We try to protect the *people by* sanitation and vaccination Likewise those of us who try to save the people from the allurem*ents of* alcohol are Baconians and we hope and believe our efforts will meet with success Personally I am *willing to acknowledge* the purity of Dr. Reid's motives. At the same time I implore him to spare *himself the unceasing* energy with which he attacks the labours of earnest temperance reformers His *attitude is* productive of no good and if he honestly feels he cannot speak words of comfort and encouragement then silence is the better part.

I am, Sirs, yours faithfully,
St. George's-terrace, Leeds, April 22nd, 1901. GORDON SHARP.

"THE TEACHING OF ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—It will probably be a couple of months before we can get Lieutenant-Colonel Lawrie's answer to Dr. Hewitt's letter in THE LANCET of April 20th, p. 1066. But as I came across yesterday, by a curious coincidence, an instruction concerning the administration of chloroform given by a foreign surgeon which supports Lieutenant Colonel Lawrie in a statement which has drawn down on him Dr. Hewitt's high scorn I beg that you will note it next week. Dr. Hewitt's quotation from Lieutenant Colonel Lawrie is: "The way to make a young child breathe regularly is to make it cry by holding the chloroform cap close down over its mouth and nose until it becomes unconscious and quiet," on which he remarks: "It is, I think, unnecessary to further criticise the above doctrines; they speak for themselves." The quotation from Léjars' "Chirurgie d'Urgence," which you recently criticised most favourably, is: "Il y a une autre méthode qui brusque les choses: la compresse, imprégnée de chloroforme, est appliquée sur la bouche et le nez et tout de suite hermétiquement fermée. Cela réussit chez l'enfant, et chez l'adulte entre des mains exercées." He goes on to say that he prefers persuasion, but that he has spoken as above shows, I think, that Lieutenant-Colonel Lawrie's views are more widely held than Dr. Hewitt supposes. If Dr Hewitt wishes to convert them he will do so more effectually by argument than by scorn.

I am, Sirs, yours faithfully,

"THE MANAGEMENT OF HOME MILITARY HOSPITALS."

To the Editors of THE LANCET.

SIRS,—Having read the article under this heading by Surgeon-Captain Pugin Thornton in THE LANCET of March 30th, p. 958, I notice that he has omitted to state what becomes of the soldier when sick *on leave* if not in the vicinity of a military hospital. Such cases are constantly cropping up in this town, and it is interesting to compare the neglect of arrangements made by the military authorities with the excellent ones in force in the navy. In the case of the soldier he is probably on furlough, staying with his family or friends. He falls ill and requires medical assistance; he is too ill to be sent to a military hospital and has therefore to be treated at home. He has to find board and lodging for himself; special diets or medical comforts, if demanded by the necessity of the case, also fall upon him. If his medical attendant gets paid for the services rendered at a critical and urgent time the soldier has to pay for them himself. But, as a matter of fact, it more often happens that the soldier requests the medical man to forward the account at the end of the attendance to his commanding officer, and the medical man, innocent of guile, having found that his bi-weekly certificates are accepted by the commanding officer, finds it a very different thing when he sends to the commanding officer the account of his fees at the end of the attendance

In the many cases that have come under my own observation no notice whatever has been taken of these accounts when duly sent in, and there appears to be no way for recovery of the fees for the attendance. In some few cases the soldier has said at the beginning that he is himself responsible for the attendance, and has done his best honestly to meet it In these cases I consider it a great tax that a soldier on leave should be obliged to pay for medical attendance just because he happens to be on furlough away from a military hospital. In one case it is unfair to the doctor, in the other unfair to the soldier.

Now let us turn to what obtains in the sister service. The navy is mostly recruited from seaport towns, and all round the coast of the British Isles there are civil surgeons appointed by the Admiralty to the medical charge of the coastguard, and it is a part of the duty of these surgeons to attend any officer or man of His Majesty's Navy who may fall sick when on leave. The surgeon is empowered to place the patient in quarters; to pay for his board and lodging, nursing, and medical comforts, if necessary; and at stated times to send in his account to the Admiralty.

I am, Sirs, yours faithfully,
CHARLES COTTON, F.R.C.P. Edin.
